CLARK — Thomas F. Clark, M.D., of Taunton, died July 24. He was in his eighty-second year.

Dr. Clark received his degree from Harvard Medical School in 1901. For twenty years prior to his retirement in 1939, he served as head of the tuberculosis clinic for the city of Taunton. He was a charter member of the Bethlehem Home Corporation and was its first physician. He was a fellow of the American Medical Association.

His sister, three nieces and a nephew survive.

MATHEWS — Robert F. Mathews, M.D., of Worcester, died July 17. He was in his sixty-ninth year.

Dr. Mathews received his degree from University of Pennsylvania School of Medicine in 1905. He was a member of the American Urological Association and a fellow of the American Medical Association.

His widow survives.

NEW HAMPSHIRE MEDICAL SOCIETY

DEATHS

PERKINS — Frank B. Perkins, M.D., of Manchester, died on June 21. He was in his ninety-fourth year.

Dr. Perkins received his degree from Dartmouth Medical School in 1877. He was the oldest living member of the Society.

A son survives.

SWEENEY — Frederick C. Sweeney, M.D., of East Jaffrey, died on June 22. He was in his eightieth year.

Dr. Sweeney received his degree from University of Vermont College of Medicine in 1895. He was a fellow of the American Medical Association.

Three sons, two daughters and sixteen grandchildren survive.

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

APPOINTMENT

James A McComb, D V M, has been appointed acting director of the Division of Biologic Laboratories, Massachusetts Department of Public Health. Dr McComb succeeds Dr Geoffrey Edsall, who has accepted the position of professor of bacteriology at Boston University School of Medicine.

Dr McComb, who has been with the Department for twenty-two years, entered the Division of Biologic Laboratories as assistant bacteriologist and a year later was appointed senior bacteriologist. He has served as assistant director of the Division since 1942.

A veteran of World War I, Dr McComb served in the Army as a sergeant in the field artillery. He was a lieutenant in the Army Reserve Corps for nine years.

He is a member of the American Veterinary Medical Association and the American Public Health Association.

RECOMMENDED PRACTICES FOR THE CONTROL OF POLIOMYELITIS

In view of the current prevalence of poliomyelitis, the Department and the Committee on Public Health of the Massachusetts Medical Society have endorsed a list of practices for the control of the disease. These practices, which were formulated by the National Conference on Recommended Practices for the Control of Poliomyelitis, held in Ann Arbor, Michigan, June, 1949, and are sponsored by The National Foundation for Infantile Paralysis, Inc., are in substance as follows:

THE DISEASE

Recognition of the Disease

Poliomyelitis is a highly prevalent infection of which only a small fraction of the cases is clinically identifiable. In its recognizable form it is an acute illness, usually febrile, with early varying symptomatology, but usually with headache and almost always a characteristic stiffness of the neck and spine that justifies an examination of the spinal fluid. In about half such cases a lower neuron paralysis develops in the first few days of illness, which shows a marked tendency for spontaneous improvement after it has reached its height. If the patient is first seen after the acute stage has passed, the diagnosis depends upon detection of a flaccid paralysis characteristically irregular in its involvement of muscle or muscle groups. Diagnosis in nonparalytic cases depends upon detection of a clinical picture compatible with the illness, plus the demonstration of a moderate increase in cells in the spinal fluid. A form of illness presumptively poliomyelitis (abortive) presenting only vague symptoms and without signs referable to the central nervous system is of frequent occurrence during epidemics.

Etiologic Agent

The poliomyelitis virus is the etiologic agent. Several immunologically distinct types have been identified.

Source of Infection

The pharyngeal and fecal discharges of infected persons, frequently those not suffering from a clinically recognized attack of the disease, constitute the source of infection.

Mode of Transmission

Close association with infected persons accounts for the great majority of cases. Outbreaks attributable to milk have been rare and limited. Although flies have been found to be contaminated with the virus, there has been no reliable evidence of spread by insects, water, food or sewage.

Incubation Period

Usually 7 to 14 days (May be from 3 to 35 days).

Period of Communicability

Apparently the period of greatest communicability is covered by the latter part of the incubation period and the first week of the acute illness.

Susceptibility and Immunity

Susceptibility to infection is general. Immunity is acquired by infection which may have been clinically inapparent. The duration of immunity is unknown, but second attacks are rare.

Prevalence

Infection is prevalent throughout the world. Paralytic cases have been apparently more frequent in the temperate zones. It occurs both sporadically and in epidemics at irregular intervals, with the highest incidence in summer and early fall. In the United States an annual incidence of 10 paralytic cases per 100,000 population is ordinary, but there is a wide variation in incidence from year to year and region to region. Children from 1 to 16 years of age are more frequently attacked than adults. In several countries, including the United States, older children and young adults constitute a higher proportion of reported cases than formerly. Even during epidemics the incidence of paralytic cases has rarely exceeded one per thousand population.

Methods of Control

- (a) Preventive measures none.
- (b) Through the infected person, contacts and environment.

Recognition of the disease by clinical manifestations assisted by microscopic and chemical examination of the spinal fluid if lumbar puncture is performed, and reporting it. In reporting, paralysis or its absence should be specified. A clear separation between these two groups of cases as reported permits a closer comparison of incidence between localities and with past experience.

Isolation for one week from date of onset, or duration of fever if longer.

Concurrent disinfections: nose and throat discharges and feces are infectious and should be disposed of as quickly and safely as possible. Articles soiled therein should be promptly disinfected.

Terminal disinfection none.

Quarantine: quarantine is of unproved value. Modified quarantine restricting the movement of intimate contacts for 7 to 14 days may be desirable in certain circumstances. (In Great Britain 21 days of exclusion from school of child contacts is required.)

Active immunization: there is none, and passive immunization is not recommended.

Investigation of source of infection: this consists of the search for and expert diagnosis of sick children to locate unrecognized and unreported cases of the disease.

- (c) Epidemic measures

General notice to physicians of the prevalence or increase of incidence of the disease, description of usual characteristics of the onset and the necessity for diagnosis and medical care, particularly for bed rest of patients, and information to the public at large on similar matters.

Isolation in bed of all children with fever, pending diagnosis.

Education in such technic of bedside nursing as will prevent distribution of infectious discharges to others from patients isolated at home

Protection of children so far as practicable against unnecessary contact with persons other than their usual associates

Postponement of elective nose or throat operations or dental extractions

Avoidance of excessive physical strain (for example, violent exercise) in children during an epidemic or in case of known exposure

Avoidance of unnecessary travel and visiting, especially of children, during a high prevalence of the infection

THE PATIENT

Reporting

All obvious and suspect cases should be promptly reported. As soon as possible all these cases should be classified as paralytic or nonparalytic. Cases which are finally diagnosed as presumptive (abortive) poliomyelitis should not be included in the final tabulation of cases by the health officers. For the guidance of health officers and physicians the following is proposed:

Diagnostic criteria of paralytic or nonparalytic poliomyelitis should generally include three or more of the following:

- History compatible with poliomyelitis
 - Fever
 - Stiff neck or stiff back or both
 - Ten to 500 cells per cc. of spinal fluid taken during the acute or early convalescent period of the disease
 - Spinal-fluid protein elevated above normal limits
 - Demonstrable muscle weakness or paralysis
- Cases that present only a history compatible with poliomyelitis, and fever, should be classified as presumptive (abortive) poliomyelitis.

Paralytic cases are defined as those in which definite weakness or paralysis has been detected and has persisted during at least two examinations with an interval of at least several hours. Results of an examination for paralysis of muscles of the extremities or trunk may be very unreliable during the period of muscle tenderness or "spasm."

Hospitalization

- (a) Admission to general hospital
Patients with acute poliomyelitis, or presumed to have acute poliomyelitis, are admissible to a general hospital provided that appropriate isolation precautions are employed. No special isolation or "pest" facilities are necessary.
- (b) Nursing care
Special-duty nurses should be employed with regard only to the medical condition of the patient, and to the number of patients they can properly handle.
- (c) Isolation technic in hospitals
The isolation procedures used for the care of acute poliomyelitis patients are similar to technics used in the hospital care of other communicable diseases, namely:

Segregation of patients having the same disease, preferably in single rooms or small wards. Patients can be cared for in large wards.

Washing of linen in the hospital laundry. Ordinary precautions for handling articles from infected persons are sufficient.

Sterilization of eating utensils after use.

Availability of toilets or hoppers in each room, small ward or large ward.

Availability of hand-washing facilities in each room, small ward or large ward.

Use of gowns by physicians when examining a patient and by nurses when caring for a patient, particularly while bedpanning.

Disposal of excreta of patients by placing in toilet or hopper as soon after passage as possible. The bedpan should be washed out if the utensil is used for a single patient, but when used in wards bedpans should be sterilized each time the utensil is used. No special treatment of feces from poliomyelitis patients is necessary.

Hand washing with ordinary soap and water should be practiced following examination of patients and after bedpanning a patient.

When toilet or hopper is situated outside the room or ward, a single pan should be covered and the contents disposed of as above. Multiple pans are best cared for by being placed on a cart and transferred to the disposal unit.

(d) Care at home

Patients may be cared for at home if home facilities and medically supervised care are adequate, or may be discharged to such home when there is no medical indication for further observation or treatment in the hospital.

Admission to or care in a hospital for isolation purposes only is not usually indicated.

(e) Care of suspect cases

It is recommended that suspect cases when admitted to a hospital should be segregated when possible from known cases until the diagnosis has been established or the patient is discharged as well.

(f) Importation of patients

In order that the best possible facilities may be used for the care of cases of poliomyelitis, patients may be sent from their own home communities to a hospital in another community. The available evidence indicates that such importation of patients into a hospital in a community where poliomyelitis is not prevalent does not effect the incidence of the disease in the hospital community.

(g) Transportation of patients

Transportation of patients from one health jurisdiction to another may be carried out under proper conditions, such as transportation in an ambulance or a private vehicle. A common carrier should not be used. Transfer should be carried out with the knowledge and the consent of the health officers in the jurisdiction to and from which the patient is being transferred.

No special treatment of ambulances after their use by poliomyelitis patients is necessary.

THE COMMUNITY

These recommendations were formulated with the emphasis on avoiding the possible effect of disturbing or altering unnecessarily the normal pattern of life in the community. Whatever is done to upset the usual routine of children in a household or adults in their occupations is likely to bring more trouble than good.

Schools

Public and private schools should not be closed during an outbreak of poliomyelitis, nor their opening delayed, except as noted below.

The closing of schools, or the delay of their opening, has not affected the course of outbreaks of poliomyelitis, moreover, such action has often resulted in panic on the part of the public. The decision to open school as usual should be announced well in advance jointly by the superintendent of schools and the health officer, in collaboration with the local medical society.

Early in the season the state departments of education and public health should issue a joint statement to which local authorities can refer for support. This statement should be issued in collaboration with the state medical society.

Exceptions

Schools to which children are transported in busses from widely separated areas may be delayed in opening if such action will prevent other close contacts among children. If these schools are not opened such action is justifiable only when other close contact among these children is not permitted in such places as theaters, picnics, playgrounds, swimming beaches or Sunday schools.

Boarding schools (excluding colleges and universities) should delay opening sessions if an outbreak of poliomyelitis exists in the area where the school is located and if the children are thus prevented from coming into the area from regions where the disease is not prevalent.

Nursery schools may be continued or closed depending upon the particular circumstances. Parents, if both are employed, may prefer to send their children to a nursery school. Parents who have facilities at home to limit contacts of young children with other children should be encouraged to keep preschool children at home.

Camps

Summer camps should be opened as usual if there is no outbreak of poliomyelitis in the area in which the camp is located.

Children should not be admitted from areas where an outbreak exists.

Inasmuch as there is no evidence that retention of children in camps where poliomyelitis exists leads to increased hazard, and that dismissal from camps may lead to spread to other communities, it is further recommended that if a case of poliomyelitis occurs in a camp the following procedures be instituted.

Retention of all children and staff at the camp for 14 days after the last contact with the case or until the usual closing date of camp.

Modified and supervised activity to prevent excessive exercise and undue mixing in group activities.

Careful medical checkup on all children daily.

Isolation of all children with fever or any suspicious signs and symptoms.

Discontinuance of admission of new children to camps in which poliomyelitis cases have been recently diagnosed.

Day camps should follow the same recommendations as those above pertaining to schools.

Places of Recreation and Amusement

It is recommended that health officers do not take action to close or prevent the operation of places of recreation or amusement, such as fairs, circuses, theaters, swimming pools or beaches, provided these are properly operated. However, the attendance of children at such places should be discouraged.

Any theoretical advantage that might be gained by closing such facilities is offset by the undesirable results of disruption of community life.

CORRESPONDENCE

ACADEMY OF GENERAL PRACTICE

To the Editor On May 26 an editorial in the *Journal* extolled the virtues of the American Academy of General Practice and the institution of a Massachusetts Chapter.

To be eligible for membership in the Academy a candidate must be a graduate of an approved medical school and have other qualifications. Several of my confreres have reminded me that the Massachusetts Medical Society and the American Medical Association grant membership and fellowship to graduates of unapproved medical schools in this Commonwealth. It would seem, then, that an Academy has been established that is not open to every reputable doctor who is qualified for membership in the organizations that sponsor said Academy. If this is not talking out of both sides of our mouths, what is?

Those of us who take responsibilities in medical organization cannot help but react to this challenge of our organization to intellectual honesty. We have seen hospitals that use the authority of the American Medical Association for their internships flagrantly disregard rulings of this same American Medical Association that helps keep them in business. Is it any wonder that individual members do not trust their organization? Is it any wonder that a sizable percentage of our membership would just as soon trust the domination of social workers and politicians as they would us?

Of course Massachusetts has a little different situation but that is no reason why we do not revolt about the point taken in this communication. Sometime this line of reasoning could lead to a qualification as to when, where, and why we were born. Those who might be considered radical in feeling the thoughts expressed here are really tremendously conservative in that they want to protect upright and hard-working, competent fellow practitioners and I am sure we would suggest that in this fight for our lives and existence, the medical profession in its organization still has not acquired the broad and liberal viewpoint that should be one of its most valuable assets.

W A R CHAPIN, M D

121 Chestnut Street
Springfield, Massachusetts

Dr Chapin's letter was submitted to Dr James G. Simmons, secretary of the Massachusetts Chapter of the American Academy of General Practice, who offers the following reply:

Dr Chapin has raised a number of questions about the American Academy of General Practice that I believe I can answer to his satisfaction.

The American Academy of General Practice is an entirely independent organization, it is not a subsidiary of the American Medical Association, nor is it connected with any state medical society. It was founded by a group of general practitioners because it appeared that there was a need for such an organization to advance the interests of the family physicians, and give them greater opportunities for education, both undergraduate and postgraduate.

However, it has had the full co-operation of the American Medical Association from the beginning. Dr Paul A. Davis of Akron, Ohio, a member of the House of Delegates and chairman of the Section on General Practice of the American Medical Association, was appointed as its official representative at the original founding meeting in June, 1947. He became the first president of the Academy.

The Board of Trustees of the American Medical Association continues to co-operate through a co-ordinating committee to which the American Medical Association appoints three members representing the Board of Trustees, the Council on Medical Service and the Council on Medical Education and Hospitals.

Whereas the by-laws of the American Academy of General Practice provide that a candidate shall be a graduate of an approved school, the same by-laws give the board of directors of each state chapter the right to make exceptions to this rule under special circumstances.

Acting under this provision most of the state chapters have taken into their organization a number of graduates of other schools on the basis of their individual qualifications, their standing in their communities and the recommendations of their fellow practitioners. It is believed that the Academy can thus best carry out its purpose of raising the quality of general medical practice throughout the country. We believe that graduates of all schools can be helped by the Academy and that they in turn can help the Academy to become a great force for good in the medical community.

If your correspondent would like any further information about the Academy, the officers of the Massachusetts Chapter would be very happy to talk with him personally or correspond with him in further detail.

JAMES G. SIMMONS, M D, Secretary

30 Myrtle Avenue
Fitchburg, Massachusetts

THE MORAL ISSUE

To the Editor Dr Leo Alexander's account of German "killers in white" in the July 14 issue of the *Journal* warns that we in this country must be on guard against a policy of inadequate treatment of dependent sick persons, mistreatment forced on doctors by an economy-minded public. But we must keep in mind that cruel and unmerciful treatment can be meted out in the very name of mercy and of religion. The atrocities committed by German doctors were acute, ours are long lasting.

Doctors who are custodians of children with undeveloped or misformed brains deny these pitiful creatures the mercy of natural death from infection. They give prophylactic inoculations and the wonderful new germ-killing drugs, and thereby force on these helpless creatures an indefinite number of miserable years. Their drawn-out misery is shared by their parents and by the many patients who could be helped but cannot gain entrance to our hopelessly clogged institutions.

I speak only of the near hairless and mindless creatures beyond reach of any medical miracle, now or ever. Doctors in charge cannot exercise their natural feeling of humanity and mercy because of the pressure of unknown popular sentiment—ignorance that doctors in general make no effort to lighten "Religious" hands raised in protest against the infectious friends of the permanently defective are, many of them, stained with the cruelly tortured blood of the Inquisition. "Be ye merciful" is a broad and compelling command.

WILLIAM G. LENOX, M D

Boston

To the Editor One of the most pertinent articles appearing in the *Journal* in recent months was in the July 14 issue, by Dr Leo Alexander, entitled "Medical Science Under Dictatorship."

One is prompted to gratitude and applause that in some quarters, at least, beyond our preoccupation with pathophysiology and health insurance, the essential values that identify a doctor have been recalled.

Dr. Alexander's careful analysis indicates what happens to the physician when he takes materialism from society and turns to view his patient. He soon embraces the attitude of "scientism" as his philosophy. The person who is the doctor's patient becomes an "organism." His tired sclerotic arteries, on which depend the perilous balance of a family livelihood, give him a number in a statistical series. Because the patient is a "case," the doctor feels no more responsibility beyond giving him a "controlled study," and the medical conscience is at peace if it sends him off with the "latest form of therapy." From this materialistic outlook on man, the level of morality of the practicing physician, such as it is, is likewise materialistic and his code then becomes "usefulness to society," utilitarianism, and rank sentimentality.

The science of medicine is one thing. The profession of medicine is quite another. The business of a practicing physician is undeniably linked to the Christian virtue of Charity. This implies the truth of man created by God. Herein lies the inherent dignity of man. From where else comes the logic of the argument against the practice of euthanasia? The hydrocephalic or the mongol may not be apparently "useful to society," but he is "useful" to God, by virtue of being His creature. Unless doctors abandon their subtle omnipotency, and realize that the values that define their profession are Christian values, their art will be reduced to a technique. Where do doctors meet this "scientism"? At the beginning—for four full years in medical school. As a recent graduate, I can vouch for the difficulty of a medical student's viewing man as anything more than viscera, muscle groups and "integrated reflexes." The honest respect that he has for his instructor's learned outline of anatomy and physiology is easily shifted to an identification with his materialistic innuendoes and—the "organism." In all the wealth of his clinical teaching, where is he told of the practice of medicine and the values underlying it? Exhortations to "treat the patient as a whole" are not enough. He must gain an idea why the patient is worth treating at all. I urge you, therefore, to look again at the medical schools.

J. JERROLD APPELGARTH, M.D.

The Roosevelt Hospital
New York City

To the Editor: You are very much to be commended for publishing Dr. Leo Alexander's excellent article, "Medical Science under Dictatorship." It not only is well written and scholarly, but does the long neglected task of pointing out fallacies in our own attitude toward medical practice.

It is reassuring to know that there are still some physicians who care about the moral aspects of the patient-doctor relation. How easy it is for us to become callous to the individual in order to perfect some technique supposedly for "the common good"! I hope that many of your readers will take his message to heart and that his acute perceptions will receive wide dissemination.

I hope, too, that this will not be the last article dealing with what may be called the philosophy of medicine. In the light of eternal values, this is really more important than the technical advances we are so careful and so prompt in reporting.

Congratulations, again, to you and to Dr. Alexander.

JAMES E. BOWES, M.D.

89-05 Hollis Court Blvd
Queens Village 8, N. Y.

THE OTHER SIDE

To the Editor: Having in mind the declaration by the Minister of Health, Mr. Bevan, in the House of Commons May 5, 1949, that "We cannot, obviously, without the most careful consideration and legal safeguards, push needles into people whether they want to have them pushed in or not," we maintain in reply to your editorial of July 7 entitled "Strange Bedfellows" that we neither lose our perspective nor depart from our apparently laudable purpose when we maintain that the right of the individual to escape vaccination or other compulsory measures can be achieved without jeopardizing the common good.

The Bill of Rights is largely concerned with the protection of the rights of minority groups, and the effect of these safeguards that are thrown around minority groups serves to provide the greatest possible protection that could be provided to majority groups. Obviously, under a system of voluntary vaccination, the unvaccinated cannot possibly expose to disease those who have been vaccinated against the disease. Since there were only 59 cases of smallpox reported in the United States in 1948 and since vaccination is not generally required in the majority of the states, the prevalence or absence of smallpox is apparently more influenced by so-called "unknown factors" than it is by compulsory vaccination in any form.

We wish to thank you for stating the purpose of the Bureau correctly and for presenting an accurate summary of our Bulletin 429.

H. B. ANDERSON, Secretary

Citizens Medical Reference Bureau, Inc.

1860 Broadway
New York City

DEPRIVATION AND RESTORATION OF LICENSES

To the Editor: At the meeting of the Board of Registration in Medicine held June 16, it was voted to revoke the registration of Dr. Earl G. Hersey of Milton.

At the meeting of the Board of Registration in Medicine held July 12, it was voted to restore the registration of Dr. Glenn F. Muntz, 6 St. Charles Street, Boston.

GEORGE L. SEHANT, M.D., Secretary
Board of Registration in Medicine

State House
Boston

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

The Skin Diseases. A manual for practitioners and students. By James Marshall, M.D., B.S., M.R.C.S., L.R.C.P., consulting dermatologist, Central Middlesex Hospital, and director of venereal diseases clinic, Royal Northern Hospital, London. 8", cloth, 363 pp., with 8 color plates. London: Macmillan and Company, Ltd., 1948. \$7.50.

In this new manual the common diseases are given extended treatment, but the whole field of dermatology is covered to some extent. Syphilis is included, as well as the nails, hair, sweat and sebaceous glands, and the mucous membrane. There is a short chapter on tumors of the skin. Recent advances in therapy have been included to bring the manual up to date. The text is well organized, and the volume well published. There is a good index.

Irregular Discharge. The problem of hospitalization of the tuberculous. Prepared by William B. Tollen, Ph.D., Research Division, Co-ordination Service, at the request of the Department of Medicine and Surgery, Veterans Administration. 8", paper, 64 pp. Washington: Veterans Administration, 1948. 20c. VA pamphlet 10-27.

In this small pamphlet a comprehensive study is made of the tuberculous patients in veterans hospitals who "walked out" or were lost track of before their required hospitalization and treatment had been completed (technically known as "irregular discharges"). Over 50 per cent of the discharges from Veterans Administration hospitals of living tuberculous patients were irregular, and only 45.6 per cent were regular. The patients with irregular discharges were still injuriously affected by tuberculosis and required further hospitalization. The problem as visualized is basically a social one for the community at large.

Synopsis of Psychosomatic Diagnosis and Treatment By Flanders Dunbar, M D With the assistance of Jacob Arlow, M D, and others, and members of the staff of the departments of medicine and psychiatry, Columbia-Presbyterian Medical Center, New York City 12°, cloth, 501 pp St Louis C V Mosby Company, 1948 \$6 50

This manual is written primarily for the general practitioner, and is intended to be a guide to the newer methods of diagnosis and treatment. An attempt has been made to follow Osler's outline, with the addition of new material to the sections on differential diagnosis and treatment. The text is well arranged, and the various chapters are written by specialists in their fields. There is a long bibliography and an extensive index. The volume is well published and should prove useful as a ready reference source.

Primary Anatomy By H A Cates, M B, professor of anatomy, University of Toronto 8°, cloth, 478 pp, with 392 illustrations Baltimore Williams and Wilkins Company, 1948 \$6 00

This new treatise on anatomy is written for nonmedical students, including nurses, physiotherapists, occupational therapists, physical educationists and other interested persons. The treatment is by systems of the body, rather than by regions, because this method is easier for the beginner. The illustrations are schematic drawings prepared especially for these groups of students. The material is well arranged, and the book well published. The type is particularly good. There is an extensive index. The volume should prove valuable to nonmedical persons.

Emergencies in Medical Practice Edited by C Allan Birch, M D, F R C P, physician, Chase Farm Hospital, Enfield 8°, cloth, 468 pp, with 113 illustrations Baltimore Williams and Wilkins Company, 1948 \$7 00

This composite work is written by nineteen specialists who have contributed articles in their special fields. The material is confined solely to emergencies of a medical character. The whole field of medicine is covered, and there are special chapters on emergencies in industrial medicine, at sea and in the air, and on medicolegal and other nonclinical emergencies. There is a good index. The volume is well published, but the use of a heavy filled paper is not justified by the two essential color plates. These could have been tipped into a lighter volume. The text was printed in Great Britain.

Hallmarks of Mankind By Frederic W Jones, D Sc, M B, B S, F R S, F R C S, Sir William Collins Professor of Human and Comparative Anatomy, Royal College of Surgeons of England 8°, cloth, 86 pp, with 23 illustrations Baltimore Williams and Wilkins Company, 1948 \$2 50

This small volume contains the subject matter of two lectures delivered by the author in 1947. It expresses his theories of the evolution of man, which he has held for over thirty years. His two main contentions are that man, "considered solely from the point of view of structure, is an extremely primitive type" and that "more primitive in basal structure than the living monkeys and apes, man has his own remarkable structural specializations that distinguish him from all other mammals and appear to be his ancient hallmarks." The text is interspersed with pertinent illustrations. The publishing is excellent. The printing was done in Great Britain. The book is a necessary source of information to all persons interested in the subject of evolution.

The Surgery of the Stomach and Duodenum By T H Somervell, M A, M B, B Ch (Cantab), F R C S (Eng), surgeon-in-charge, London Mission Hospital, Neyoor, S India, and examiner in surgery to the University of Madras 8°, cloth, 546 pp, with 231 illustrations Baltimore Williams and Wilkins Company, 1948 \$11 00

The author of this special work on surgery had an extensive experience in India, where gastric and duodenal diseases are very prevalent. He believes that ligation of the gastric vessels and even vagotomy are preferable to gastrectomy for the average surgeon. His work is based on the literature of the subject, as well as his vast experience. Likewise, Dr Somervell is impressed with the future of the transthoracic operation for surgery of the upper abdomen and especially the trans-

diaphragmatic method of Dr Gardham, of London. These operations are described in detail in the chapter on esophago-gastric conditions. The text is well organized. The preliminary chapters are devoted to embryology, anatomy, physiology, pain, diagnosis and operative methods in general. The following chapters deal with the various diseases and conditions of the stomach and duodenum. There is a special chapter on the gallbladder and pancreas in relation to gastroduodenal surgery. Short lists of selected references are appended to the various chapters, and a bibliographic index lists the authors of the references in alphabetical order. There is also a good index of subjects. The illustrations were mostly drawn by the author. The text was printed in Great Britain, and the type and printing are excellent. The book should be in all medical libraries and available to all surgeons interested in gastric and abdominal surgery.

Medical Manual By William R Feasby, M D, medical assistant to the superintendent, The Toronto Western Hospital, and lecturer in physiology, University of Toronto 16°, cloth, 162 pp Toronto University of Toronto Press, 1948 \$2 25

This small manual is intended primarily for senior students, interns and nurses. The text is intentionally brief, but an effort has been made to include the information needed for everyday use. The greater part of the text is devoted to materia medica, diet and clinical methods. There is a special chapter on legal considerations. There is a list of common diagnoses and a good index. The manual compares favorably with similar publications.

Physicians' Federal Income Tax Guide For the preparation of 1948 returns and 1949 estimates By Hugh J Campbell and James B Liberman 1948-49 edition 4°, paper, 96 pp Great Neck, New York Doniger and Raughley, Incorporated, \$2 50

This valuable manual should be owned by every physician. It explains in detail how to make out tax returns and estimates. The tables of professional deductions, nontaxable receipts and nonprofessional deductions are especially valuable. The pamphlet is well published.

Allergy to Cottonseed and Other Oilseeds and Their Edible Derivatives. Excerpts from testimony before the administrator, Federal Security Agency. In the matter of fixing and establishing definitions and standards of identity for mayonnaise, French dressing, and related salad dressings (docket FDC-51). Public hearing held at Washington, D C, November 18, 1947 and January 6 to 8, 1948 8°, cloth, 275 pp Memphis, Tennessee National Cottonseed Products Association, Incorporated, 1948 Free

This volume contains the testimony of 6 expert witnesses on allergy to cottonseed oil and other oilseed products, and of 2 other experts concerning relevant factors of vegetable-oil technology. The testimony was given at public hearings held before the Federal Security Administrator on November 18, 1947, and January 6-8, 1948, in the matter of fixing and establishing definitions and standards of identity for mayonnaise, French dressing and related salad dressing. The evidence presented had to do with allergy to edible oils. The edition was limited to 500 copies and presented to all medical schools in the United States and to selected medical and scientific libraries with the intention of making the volume available to all interested persons. It is not for sale.

The British Encyclopaedia of Medical Practice, Including Medicine, Surgery, Obstetrics, Gynaecology, and Other Special Subjects (Medical Progress 1948) Editor-in-chief, Rt. Hon Lord Horder, G C V O, M D, B Sc., F R C P, physician to the King, and consulting physician to St Bartholomew's Hospital 8°, cloth, 539 pp, with 5 illustrations London Butterworth and Co (Publishers), Ltd, 1948

This volume is the latest of a long series intended to portray the advances in medicine for the year 1948. It is issued to supplement the encyclopedia, and the series brings this large work up to date.

Clinical Urology Essentials of diagnosis and treatment By Lowrain E. McCrea, M.D., F.I.C.S., clinical professor of urology, Temple University School of Medicine, and attending urologist, Philadelphia General Hospital. Second edition. 8°, cloth, 503 pp., with 263 illustrations. Philadelphia: F. A. Davis Company, 1948. \$6.50.

The first edition of this book was published in 1946, and the demand for a new edition so soon is evidence of its soundness and popularity. The text, which has been brought up to date and in a large part rewritten, is based solely on the experience, practice and opinions of Dr. McCrea. The volume is well published. The type is excellent, making for easy reading. There is an extensive index. The use of a coated paper makes the volume rather heavy for its size. The book should be in all medical libraries and should prove useful to all physicians interested in urology.

Acta Radiologica Supplementum 65 Intussusception in Children. Diagnosis and therapy with barium enema By Hans Hellner. 4°, paper, 120 pp., with 50 illustrations and 6 tables. Lund, Sweden: Hakan Ohlssons Boktryckeri, 1948. Swed. Crowns 15.—

Supplementum 68 Carcinoma of the Tongue. A clinical study of 277 cases treated at Radiumhemmet, 1931-1942 By Folke Jacobsson. 4°, paper, 190 pp., with 24 illustrations. Stockholm: Esselte Aktiebolag, 1948. Swed. Crowns 20.—

Supplementum 69 A Pneumographic Study of the Temporal Horn. With special reference to tumours in the temporal region By Erik Lindgren. 4°, paper, 151 pp., with 239 illustrations. Stockholm: P. A. Norstedt and Sons, 1948. Swed. Crowns 25.—

Supplementum 70 Studies on Back-flow in Excretion Urography By Olle Olsson. 4°, paper, 80 pp., with 18 illustrations. Lund: Hakan Ohlssons Boktryckeri, 1948. Swed. Crowns 20.—

Supplementum 71 On the Transmission Through Skin of Visible and Ultraviolet Radiation By K. G. Hansen. 4°, paper, 106 pp., with 84 illustrations. Copenhagen, Denmark: Arnold Busck, 1948. Swed. Crowns 8.—

These supplements are all written in English and present the latest information on the subjects under consideration.

Language and Language Disturbances. Aphasic symptom complexes and their significance for medicine and theory of language By Kurt Goldstein, M.D. 8°, cloth, 374 pp. New York: Grune and Stratton, 1948. \$8.75.

This monograph on aphasia is divided into two main parts: the origin of aphasic symptoms, and case reports, pathologic anatomy, and treatment. The discussion of treatment is limited to twenty pages. The literature of the subject is referred to throughout the text. The material is well organized and well presented. The book is well published and should be in the reference collections of all medical libraries and available to all neurologists. There is a bibliography of 332 items, as well as indexes of authors and subjects.

The Shame of the States By Albert Deutsch. 8°, cloth, 188 pp., with illustrations. New York: Harcourt, Brace and Company, 1948. \$3.00.

In this small volume Mr. Deutsch presents a camera-documented story of conditions in the public mental hospitals in the United States. During a period of eighteen months the author visited thirty state hospitals from coast to coast, and found shocking conditions in many. On some of the visits the author was accompanied by news photographers, and some of the pictures taken are reproduced in the volume. In two chapters the United States Army's Mason General Hospital, at Brentwood, New York, and the Brooklyn State Hospital are described as two of the better hospitals, despite the overcrowding at Brooklyn. Mr. Deutsch conferred with many experts, who could not point to any hospital as being the best in the land. All had their deficiencies, but, according to the author, "the fact is that not a single state mental hospital in the whole country meets all the minimum standards of care and treatment, established twenty years ago by the American Psychiatric Association." The concluding chapters have to do with the efforts to remedy the existing deplorable conditions.

The Case Against Socialized Medicine. A constructive analysis of the attempt to collectivize American medicine By Lawrence Sullivan. 12°, cloth, 53 pp. Washington: The Statesman Press, 1948. \$1.50.

Mr. Sullivan, in this small book, presents in short chapters a historical account of socialized medicine. The story is based principally on the sworn testimony of witnesses appearing before committees of the House and Senate.

NOTICES

ANNOUNCEMENTS

Dr. Salvador Jacobs announces the opening of offices at 66 Rogers Avenue, Lynn, and 416 Marlborough Street, Boston, for the practice of neurology and general psychiatry.

Dr. Frederick Rosenheim, formerly associated with the Judge Baker Guidance Center, announces the opening of an office at 122 Commonwealth Avenue, Boston, on September 6.

Dr. Nathaniel M. Stone, of 371 Commonwealth Avenue, Boston, will continue the x-ray practice of his former associate, Dr. John W. Meachen, at 332 Pleasant Street, Malden. Offices will be open at both addresses.

Dr. George J. Warren announces the opening of an office at 55 Broad Street, Lynn, for the practice of urology.

MASSACHUSETTS STATE SOCIETY OF EXAMINING PHYSICIANS

A meeting of the Massachusetts State Society of Examining Physicians will be held on Wednesday, November 16, at 6:30 p.m., at the Harvard Club in Boston. Following the dinner, Dr. Fred Jostes of St. Louis, Missouri, will present a paper on rehabilitation.

All physicians are cordially invited to attend.

TRAINING IN PSYCHIATRY

The United States Public Health Service under the National Mental Health Act has approved a grant for a trainee in psychiatry at the Walter E. Fernald State School situated 8 miles from Boston. The stipend is level 5, or \$3000 per year. However, candidates at lower levels may be considered and the amount of the stipend adjusted to the level of the candidate's training. Training will be offered in mental deficiency, child psychiatry, and related psychiatric and neurological problems through supervised experience in the out-patient, in-patient, research laboratory, psychological, educational and social-service departments, as well as participation in staff meetings, seminars in basic psychiatry and neurology and in child psychiatry.

Applications including the candidate's qualifications or requests for further information should be forwarded to Dr. Malcolm J. Farrell, Superintendent, Walter E. Fernald State School, Waverley 78, Massachusetts.

MEDICAL CONSIDERATIONS IN THE CARE OF ELDERLY PATIENTS WITH HIP FRACTURES*

ROBERT J. FAHEY, M.D.,† RICHARD M. KILFOYLE, M.D.,‡ AND JOSEPH H. SHORTELL, M.D.§

BOSTON

IN SHARP contrast to the attitude of a few years back, hip nailing in aged people suffering from various medical disabilities has become accepted surgical practice. Penicillin, carefully controlled anesthesia, the use of blood and standard physiologic fluids, refinements of surgical technic and early ambulation have permitted feats of major surgery previously believed impossible, especially in the aged. In the cases of hip fracture, traction or a plaster spica was used by choice under the impression that operation was too great a risk in this age group. This attitude is now reversed, and nailing is performed to avoid the many evils of prolonged bed rest and traction, to diminish the burdens on an already overtaxed nursing staff and, most important, to lower an appalling mortality rate.

The serene course of some patients with even critical medical conditions both during and after operation has been surprising. With good medical care and follow-up study and careful selection of patients and time of operation, a satisfactory outcome is now expected. Nevertheless, some deaths have occurred postoperatively in patients who were judged acceptable for hip nailing—usually from conditions that were present before the operation or even the fracture. The most important medical factors, therefore, have not been emphasized in the literature on hip fracture. No criteria have been established regarding selection of the patient and the time of operation or what definite measures can be taken under specific circumstances to facilitate surgery or make it possible.

To clarify our thoughts in the matter with the purpose of holding operative mortality to a minimum we studied the records of 100 consecutive patients who had attained the age of seventy or over, who were treated on the Sixth Surgical Service, Boston

City Hospital for fracture of the hip. The periods of treatment were between November, 1944, and January, 1948. This was a period in which penicillin was in general use—a factor that, we believe, had an important bearing on the general clinical course. No attempt was made to include follow-up studies inasmuch as this paper deals with the medical care in the hospital until the patient is ready for discharge.

In this series, the operation of nailing was done by one of two methods—"open" in the operating room or by the so-called "closed" method under the fluoroscope. The first was more frequently used.

The patient was given light premedication and was transported to the operating room with the injured limb supported on a Thomas splint. Low spinal anesthesia of light dosage was given, and intravenous injection of saline solution was started and allowed to run slowly.¹ Two pints of blood were ready if needed. The fracture was reduced by a suitable method, a modified Leadbetter maneuver or, in the cases of some intertrochanteric fractures, traction with internal or external rotation. X-ray films taken with a portable apparatus were used to check the position. After skin preparation and draping, the upper femoral shaft was approached through a straight or curved lateral incision, deepened through fascia lata and vastus lateralis. Sufficient periosteum was elevated to permit insertion of two Bennett retractors. Fixation depended on the type of fracture and the judgment of the operator. Kirschner wires and x-ray films taken with a portable apparatus were used to find proper length and direction.

The "closed" method was performed in the dark room with the aid of the fluoroscope. Reduction may be checked by a film taken with the cassette placed in the viewing screen. Kirschner wires were then drilled across the fracture site through the prepared skin. An incision 2.5 cm. in length, was made down to bone around the correctly placed wire. A cannulated Smith-Petersen nail was threaded over the wire and driven home. This procedure

*Presented in part at the annual meeting of the American College of Surgeons, Committee on Fractures and Other Traumas, Boston, January 29, 1949, and at the Boston City Hospital postgraduate course in fractures conducted by Sir Reginald Watson Jones, May, 1948.

†From the Sixth Surgical and the Third Medical Services, Boston City Hospital.

‡Instructor in medicine, Tufts College Medical School; formerly resident, Third Medical Service (Tufts), Boston City Hospital.

§Assistant resident, Children's Hospital, Children's Medical Center; formerly resident, Sixth Surgical Service, Boston City Hospital.

§Instructor in orthopedic surgery, Harvard Medical School; surgeon-in-chief, Boston City Hospital; chief, Sixth Surgical Service, Boston City Hospital.

could be completed very often in thirty or forty minutes, which, together with the minimal operative trauma, constituted its chief advantage.

Postoperative care was aimed to get the patient either out of bed or moving about freely in bed as soon as possible, and as soon as strength and freedom from pain allowed. Sometimes a day or two after operation a woman in her middle eighties was up in a chair, surprised and smiling at how well she felt. Quadriceps exercises and knee motion were encouraged, daily check was made for common complications, especially calf tenderness, pain and foot edema. Again, when strength was sufficient, usually a matter of two or three weeks, the patient was allowed up in a walker and then on crutches under supervision. The foot on the injured side was placed on the floor, with very little or no weight bearing, to avoid the awkwardness of crutch walking with the hip and knee flexed.

Time of discharge depended on many factors, most of them social.

Seventy-two of the 100 patients were operated upon. Twenty-eight were treated conservatively either by traction or by application of a plaster spica. Conservative treatment was instituted be-

few hospital days. In the first group were good operative risks, in the second fair operative risks and in the third patients on whom operation was contraindicated.

Group I

In Group I we placed patients who, in spite of their age, were in good physical condition. They tolerated surgery very well and required only the usual preoperative and postoperative care. Unfortunately, this was a small group. In our series of 100 cases, 13 fell into this category. There was no mortality. The following case is typical.

E. Q., a 76-year-old woman, entered the hospital on December 5, 1946, with a history of having slipped and fallen on her porch on the day prior to entry. After this accident she noted pain in the left hip and inability to stand. Physical examination showed shortening and external rotation, with painful motion of the left hip. The lungs were clear, the heart was not enlarged, and the rate and rhythm regular, with a soft apical systolic murmur. The blood pressure was 140/70. Routine laboratory work was negative. X-ray study showed an intertrochanteric fracture of the left hip. The patient remained in excellent physical condition in Russell traction. On the 5th day a Smith-Petersen nail with a Thornton atachment was inserted uneventfully. Anatomic reduction was obtained. The postoperative course was uneventful, and the patient was discharged on the 17th hospital day, on crutches, to be followed at home by her own doctor.

Group II

Group II included patients who showed the scars of aging. They had underlying physical disabilities that required active and prompt medical treatment prior to operation, cautious anesthetic and operative handling and a close postoperative follow-up study. That hip fracture in the elderly is very often as much a medical as a surgical problem can be seen from the fact that 70 cases fell into this group.

Four patients in this group died. A typical case is as follows.

S. M., an 83-year-old woman, entered the hospital on April 12, 1947, with a complaint of pain in the right hip after a fall on the night prior to admission. She also gave a history of long-standing diabetes and hypertension. The diabetes had been treated with diet alone, but she had been taking digitalis intermittently for the past year. Physical examination revealed a well developed woman in no apparent distress. The lungs showed moist rales at both bases. The heart border was enlarged to the anterior axillary line, and there was a rough, Grade III systolic murmur. The blood pressure was 190/100. There was shortening and external rotation of the right leg. The urine showed an orange Benedict reduction, and the sediment was loaded with white blood cells. Examination of the blood disclosed a hemoglobin of 65 per cent and a white-cell count of 8600. The blood sugar was 250 mg., and the nonprotein nitrogen 42 mg. per 100 cc., and the carbon dioxide combining power 49 per cent. X-ray examination showed an intertrochanteric fracture of the right femur. The right leg was placed in Russell traction, and immediate attempts to restore cardiac compensation and regulate the diabetes were instituted. The patient was given penicillin and sulfadiazine to combat the urinary-tract infection. By the 16th hospital day the diabetes was under good control, all evidence of cardiac decompensation had cleared, and the urine sediment was normal. She was then operated upon under spinal anesthesia. Smith-Petersen nail with a Thornton plate was successfully inserted. The postoperative course was smooth, and she was out of bed on the 4th postoperative day and discharged from the hospital on the 58th hospital day on crutches.

TABLE 1 Medical Grouping of All Patients

GROUP	STATUS OF PATIENT	SURVIVALS	DEATHS	TOTALS
I	No detectable disease process	13	0	13
II	Mild to moderate reversible conditions	64	6	70
III	Severe, nonreversible conditions becoming worse	0	17	17

cause of personal choice of the attending surgeon, because of the nature of the fracture or because the patient was considered a poor surgical risk. Sixty-one had intertrochanteric fractures, and 39 fractures of the femoral neck. Of the patients operated upon, 13 died—a mortality of 18 per cent. In the group treated conservatively there were 9 deaths—a mortality of 32 per cent. The high mortality in this group reflects the fact that it included many poor-risk patients. The average time in the hospital prior to surgery was nine and four-tenths days. The patients operated on were out of bed, on the average, in twelve and five-tenths days, and those treated conservatively in forty-one days. The average hospital stay was forty-five days for the operated patients and seventy-seven days for those treated conservatively. These statistics differ little from reports of several other large clinics.²⁻⁸

No attempt has been made to correlate the type of fracture with the mortality.

We have found that our cases could be classified into three groups (Table 1), depending upon the amount and type of concomitant medical disability existing as observed during their first

Group III

Group III comprised patients with severe and extensive medical problems who, under adequate medical management, showed no evidence of improvement or were becoming worse under conservative treatment. The trauma of hip fracture tipped the balance in these elderly people in much the same manner that a bronchopneumonia becomes the terminal event in the elderly patient with cardiac disease. Seventeen patients fell into this group, 9 were operated upon, and 8 were treated conservatively, all died. The following case is typical.

H. E., a 77-year-old woman, entered the hospital on January 21, 1945. On the day of admission she had tripped and fallen on her right hip, sustaining a fracture of the right femoral neck. Physical examination showed an elderly, unco-operative woman in moderate pain. The lungs demonstrated bilateral moist rales at the bases. The cardiac border extended to the left, the sounds were of poor quality, and there were rough systolic murmurs at both apex and base. The peripheral arteries showed evidence of marked arteriosclerosis, and the eyegrounds consistent changes. The blood pressure was 160/110. There was shortening and external rotation of the right leg. The urine was normal. Examination of the blood disclosed a hemoglobin of 57 per cent and a white-cell count of 7200. The blood Hinton reaction was negative. The nonprotein nitrogen was 43 mg, and the fasting blood sugar 110 mg per 100 cc.

The patient was placed in Russell traction. When seen by a medical consultant shortly after admission she was found to be in marked congestive failure. She was placed on a salt-poor diet and given ammonium chloride, mercurpurin, digitalis and sulfadiazine. She did not improve under this regimen and became more and more unco-operative. Her course was downhill, cardiac failure persisting. A bronchopneumonia developed, and she died on the 22nd hospital day.

In our opinion operation would not have changed the outcome in this case.

TABLE 2 Conditions Existing before Operation in 72 Cases*

CONDITION	NO OF CASES	SURVIVALS*	DEATHS†
Cardiovascular disease	41	31	10
Decubitus ulcer	9	8	1

Pernicious anemia	1	1	0

*Total of 59 cases

†Total of 13 cases

Table 2 lists the recorded underlying diseases that, in various combinations, were found in the 72 patients undergoing operation. It is immediately

apparent that cardiovascular disease was the greatest complicating factor. Forty-one cases were diagnosed as either arteriosclerotic heart disease or hypertensive heart disease, or both. No cases of rheumatic or syphilitic heart disease were encountered, as might be anticipated in this age group. Ten of these 41 patients were in congestive failure. Other medical disabilities having a direct effect on the outcome were diabetes, pneumonia, uremia and psychoses.

Table 3 demonstrates the effect of congestive failure on the mortality and points out that the

TABLE 3 Arteriosclerotic and Hypertensive Heart Disease in 41 Patients Operated Upon

STATUS	NO OF CASES	SURVIVALS	DEATHS
Compensated	28	26	2

Gangrene of involved extremity	2	0	2
Psychosis	5	2	1
Decubitus ulcer	7	5	2
Gastrointestinal hemorrhage (carcinoma of stomach)	1	0	1

cluded in this list. Noteworthy is the high incidence of pulmonary complications such as pneumonia, atelectasis and emboli. Circulatory failure developed in only 3 cases.

DISCUSSION

Preoperative Study

In medical evaluation certain points in the history and physical examination are of special concern.

History. One should determine, in eliciting the present illness, whether the trauma was a result of a simple accident, such as tripping or slipping, or whether the patient fell because of a "fainting spell." In this age group such spells are often due to serious

could be completed very often in thirty or forty minutes, which, together with the minimal operative trauma, constituted its chief advantage.

Postoperative care was aimed to get the patient either out of bed or moving about freely in bed as soon as possible, and as soon as strength and freedom from pain allowed. Sometimes a day or two after operation a woman in her middle eighties was up in a chair, surprised and smiling at how well she felt. Quadriceps exercises and knee motion were encouraged, daily check was made for common complications, especially calf tenderness, pain and foot edema. Again, when strength was sufficient, usually a matter of two or three weeks, the patient was allowed up in a walker and then on crutches under supervision. The foot on the injured side was placed on the floor, with very little or no weight bearing, to avoid the awkwardness of crutch walking with the hip and knee flexed.

Time of discharge depended on many factors, most of them social.

Seventy-two of the 100 patients were operated upon. Twenty-eight were treated conservatively either by traction or by application of a plaster spica. Conservative treatment was instituted be-

few hospital days. In the first group were good operative risks, in the second fair operative risks and in the third patients on whom operation was contraindicated.

Group I

In Group I we placed patients who, in spite of their age, were in good physical condition. They tolerated surgery very well and required only the usual preoperative and postoperative care. Unfortunately, this was a small group. In our series of 100 cases, 13 fell into this category. There was no mortality. The following case is typical.

E. Q., a 76-year-old woman, entered the hospital on December 5, 1946, with a history of having slipped and fallen on her porch on the day prior to entry. After this accident she noted pain in the left hip and inability to stand. Physical examination showed shortening and external rotation, with painful motion of the left hip. The lungs were clear, the heart was not enlarged, and the rate and rhythm regular, with a soft apical systolic murmur. The blood pressure was 140/70. Routine laboratory work was negative. X-ray study showed an intertrochanteric fracture of the left hip. The patient remained in excellent physical condition in Russell traction. On the 5th day a Smith-Petersen nail with a Thornton attachment was inserted uneventfully. Anatomic reduction was obtained. The postoperative course was uneventful, and the patient was discharged on the 17th hospital day, on crutches, to be followed at home by her own doctor.

Group II

Group II included patients who showed the scars of aging. They had underlying physical disabilities that required active and prompt medical treatment prior to operation, cautious anesthetic and operative handling and a close postoperative follow-up study. That hip fracture in the elderly is very often as much a medical as a surgical problem can be seen from the fact that 70 cases fell into this group.

Four patients in this group died. A typical case is as follows.

S. M., an 83-year-old woman, entered the hospital on April 12, 1947, with a complaint of pain in the right hip after a fall on the night prior to admission. She also gave a history of long-standing diabetes and hypertension. The diabetes had been treated with diet alone, but she had been taking digitals intermittently for the past year. Physical examination revealed a well developed woman in no apparent distress. The lungs showed moist rales at both bases. The heart border was enlarged to the anterior axillary line, and there was a rough, Grade III systolic murmur. The blood pressure was 190/100. There was shortening and external rotation of the right leg. The urine showed an orange Benedict reduction, and the sediment was loaded with white blood cells. Examination of the blood disclosed a hemoglobin of 65 per cent and a white-cell count of 8600. The blood sugar was 250 mg., and the nonprotein nitrogen 42 mg. per 100 cc., and the carbon dioxide combining power 49 per cent. X-ray examination showed an intertrochanteric fracture of the right femur. The right leg was placed in Russell traction, and immediate attempts to restore cardiac compensation and regulate the diabetes were instituted. The patient was given penicillin and sulfadiazine to combat the urinary-tract infection. By the 16th hospital day the diabetes was under good control, all evidence of cardiac decompensation had cleared, and the urine sediment was normal. She was then operated upon under spinal anesthesia. Smith-Petersen nail with a Thornton plate was successfully inserted. The postoperative course was smooth, and she was out of bed on the 4th postoperative day and discharged from the hospital on the 58th hospital day on crutches.

TABLE 1 Medical Grouping of All Patients

GROUP	STATUS OF PATIENT	SURVIVALS	DEATHS	TOTALS
I	No detectable disease process	13	0	13
II	Mild to moderate reversible conditions	64	6	70
III	Severe, nonreversible conditions becoming worse	0	17	17

cause of personal choice of the attending surgeon, because of the nature of the fracture or because the patient was considered a poor surgical risk. Sixty-one had intertrochanteric fractures, and 39 fractures of the femoral neck. Of the patients operated upon, 13 died—a mortality of 18 per cent. In the group treated conservatively there were 9 deaths—a mortality of 32 per cent. The high mortality in this group reflects the fact that it included many poor-risk patients. The average time in the hospital prior to surgery was nine and four-tenths days. The patients operated on were out of bed, on the average, in twelve and five-tenths days, and those treated conservatively in forty-one days. The average hospital stay was forty-five days for the operated patients and seventy-seven days for those treated conservatively. These statistics differ little from reports of several other large clinics.^{2,8}

No attempt has been made to correlate the type of fracture with the mortality.

We have found that our cases could be classified into three groups (Table 1), depending upon the amount and type of concomitant medical disability existing as observed during their first

nonia have had pulmonary emboli from silent thromboses in the legs. It is important to realize that in the aged the manifestations of peripheral venous thrombosis and pulmonary embolization may be minimal and may be unrecognized unless sought for quite diligently.

Pulmonary Factors

Although failure of the cardiovascular system predominated as a cause of death, pulmonary complications were of importance (Table 4). Just as the vascular system becomes inelastic so also does the thoracic cage. The costal cartilages become calcified, and changes occur in the intervertebral disks of the thoracic spine, with ensuing deformities that contribute to the rigidity of the chest wall and lead to emphysema. The net results are poor respiratory mechanics, with improper drainage of the bronchial tree and thus a predisposition to pneumonia and atelectasis. Hence one must expect and try to prevent the occurrence of these complications. An expectorant such as potassium iodide may be used to thin out the bronchial secretions and prevent obstruction of bronchi with tenacious plugs of mucus. Deep breathing should be encouraged, and as much painless motion as possible in traction should be instituted. Exposure of the patient to upper respiratory infection should be scrupulously avoided. The use of penicillin both before and after operation has been of tremendous help in the prevention and treatment of lung infection.

Renal Factors

Renal factors deserve special attention in the elderly age group. Shock¹⁰ has shown in a study of elderly men that inulin clearance, a measure of glomerular filtration, is 60 per cent of normal, whereas Diodrast clearance which gives a more complete over-all picture of kidney function is decreased to 45 per cent of normal. The recent work of Trueta et al.¹¹ in demonstrating the renal shunt mechanism following fractures of extremities and other noxious stimuli makes it evident that trauma, with its concomitant shock may further decrease renal function to the point of serious decompensation. We have found that operation on a patient with an elevated or rising nonprotein nitrogen can have disastrous results. Of similar importance is the carbon dioxide combining power of the blood. One of the prime functions of the kidney is the regulation of the acid-base equilibrium of the body. It does this by a process of selective retention or excretion of various salts. An early manifestation of impaired function is often a loss of this fine discriminatory power. As a result there is a retention in the body of sulfates and phosphates at the same time that there is a loss of fixed base. This can lead to a rather severe acidosis which must be corrected prior to operation. If the nonprotein nitrogen is high or the carbon dioxide low

the condition is corrected preoperatively by the use of fluids, sodium lactate or bicarbonate and saline solution as indicated. If there is no chemical improvement or still further deterioration, operation should not be performed.

Renal-tract infection was seen in 10 of the 72 patients operated on either before or after surgery. It is important to maintain an adequate urine flow both in the prevention and in the treatment of this condition. In men urinary retention secondary to prostatic obstruction must be avoided, and constant drainage should be instituted whenever there are signs and symptoms of such a difficulty.

Complete studies on water and electrolyte balance have been presented by Maddock and Coller.^{12, 13} Sufficient fluid should be administered either by mouth or parenterally to maintain a urine output of 1000 to 1500 cc daily.

Diabetes Mellitus

There were 7 diabetic patients in the group. Of these 3 died. As a rule the elderly patient with diabetes of long standing presents a hazardous problem to both the surgeon and the internist. McKittrick¹⁴ has pointed out the necessity of more deliberate and careful preparation for operation on patients with diabetes. The 3 fatal cases were never well controlled, and the patients showed elevated blood sugars and continually lost large amounts of sugar in the urine. In 2 cases gangrene of the involved limb occurred and all 3 patients succumbed to overwhelming infection.

SUMMARY

A study of 100 patients over the age of seventy admitted to the Boston City Hospital with hip fractures revealed a significant number with pre-existing medical disabilities. A grouping of the cases according to type and severity of such disabilities and the response to medical therapy is presented. Group I comprised good surgical risks, Group II fair risks, and Group III patients on whom operation was contraindicated. The effect on the mortality rate of degenerative diseases in the cardiovascular, pulmonary and renal systems and the management of these diseases are discussed.

underlying disease involving the cardiovascular system

In senescence degenerative changes take place throughout the body, leaving the various organ systems prone to breakdown at periods of stress and strain. Special attention should be given to symptoms referable to the cardiovascular, renal and pulmonary systems. Evaluation of cardiac cases depends a great deal on the history. This has been emphasized by Sprague,⁹ who points out that the history is of more importance than the stethoscope or electrocardiogram. Patients who have led normal, active lives with no symptoms of cardiac failure will offer no cardiac problem to the surgeon. On the other hand, patients whose activities have been restricted because of dyspnea or chest pain may be hazardous surgical risks. Dyspnea or cough may also indicate decreased pulmonary reserve. Renal disease may be manifested only by a history of polyuria or nocturia.

Physical examination. Mere inspection of the patient tells a great deal. Is the patient oriented? Disorientation is often the only manifestation of a cerebrovascular accident. Shock, which is present in all cases to a greater or lesser degree, may cause mild to severe changes. The patient who is oriented and who lies flat in bed in traction with no increase in respiratory rate will usually prove a good surgical risk.

An enlarged heart or the presence of murmurs in no way contraindicates surgery provided cardiac compensation is present. Cardiac rhythm is of special concern. Such arrhythmias as auricular fibrillation and premature ventricular systoles demand special attention and treatment.

Adequate examination of the lungs is difficult in these cases. The finding of rales is usually ominous. They may be due to shock or myocardial failure, or both, and may indicate hypostatic changes with infection. All these conditions require prompt adequate treatment.

Abdominal distention is occasionally seen after hip fracture. Causes such as incipient intestinal obstructions, uremia and cerebrovascular accident should be considered alongside post-traumatic ileus.

Laboratory data. The following studies are recommended: complete urinalysis, hemoglobin determination, red-cell count, white-cell count and differential, blood nonprotein nitrogen, fasting blood sugar and blood carbon dioxide combining power. An electrocardiogram is often indicated.

Evaluation of the patient as a surgical risk will frequently require twenty-four to forty-eight hours or longer. During this period shock is corrected, fluid balance is established, and the patient is placed in optimum condition to withstand operation. On the basis of the history, physical examination, laboratory studies and response to therapy the patient can be classified in one of the three groups proposed. Only patients in Group III should be re-

fused operation. If a patient is becoming worse under adequate medical management in traction, we do not believe that operation will in any way alter the course for the better. On the contrary, it will undoubtedly hasten death.

Cardiovascular Factors

The incidence of cardiovascular disease, of either the hypertensive or the arteriosclerotic type, is notably high in elderly patients. Their cardiac reserve is low, and they are easily thrown into congestive failure or shock by the altered circulatory dynamics following the trauma of hip fracture. No operation should be attempted on such patients until the cardiac failure has been corrected. Once this has been accomplished, no type of heart disease except recent myocardial infarction is a contraindication to hip nailing.

The routine use of digitalis in patients who are not in failure should be avoided, since it decreases cardiac output and increases the irritability of the myocardium and hence predisposes to the development of ventricular tachycardia or fibrillation. If there is any evidence of ventricular irritability, such as ventricular extrasystoles, the patient should be given 0.2 to 0.3 gm (3 to 5 gr) of quinidine every four hours. This drug is efficacious in preventing fatal cardiac arrhythmias that might develop during operation.

The vascular degenerative changes in the aged predispose to shock as a result of trauma. The widespread arteriosclerosis — and, therefore, the diminished elasticity and adaptability of the vascular system — does not permit the compensatory changes seen in the younger age group. Because of this, shock must be treated as early and as adequately as possible. This lowered capacity of the vascular system for adaptation should be kept in mind when fluids are administered intravenously, for a sudden increase in circulatory volume in these patients may be fatal.

The danger of arterial thrombosis is ever present. Although the occurrence of massive myocardial infarction is not common in the aged, there may be extensive small thromboses in branches of the main coronary arteries, and in spite of lack of chest pain and electrocardiographic changes, the patient may die of coronary-artery insufficiency. Thrombosis of arteries in the brain may be accompanied by no peripheral neurologic signs, the only manifestation of this catastrophe being a change in character or sensorium, abdominal distention or, worse, the development of a frank psychosis. Shock by slowing of the blood flow enhances the possibility of thrombosis in this age group.

Eleven of the patients operated on showed signs and symptoms of thrombophlebitis or phlebothrombosis. In these cases pulmonary emboli developed in 2, who died. This is a rather low figure, and it is quite possible that patients believed to have pneu-

monia have had pulmonary emboli from silent thromboses in the legs. It is important to realize that in the aged the manifestations of peripheral venous thrombosis and pulmonary embolization may be minimal and may be unrecognized unless sought for quite diligently.

Pulmonary Factors

Although failure of the cardiovascular system predominated as a cause of death, pulmonary complications were of importance (Table 4). Just as the vascular system becomes inelastic, so also does the thoracic cage. The costal cartilages become calcified, and changes occur in the intervertebral disks of the thoracic spine, with ensuing deformities that contribute to the rigidity of the chest wall and lead to emphysema. The net results are poor respiratory mechanics, with improper drainage of the bronchial tree and thus a predisposition to pneumonia and atelectasis. Hence one must expect and try to prevent the occurrence of these complications. An expectorant such as potassium iodide may be used to thin out the bronchial secretions and prevent obstruction of bronchi with tenacious plugs of mucus. Deep breathing should be encouraged, and as much painless motion as possible in traction should be instituted. Exposure of the patient to upper respiratory infection should be scrupulously avoided. The use of penicillin both before and after operation has been of tremendous help in the prevention and treatment of lung infection.

Renal Factors

Renal factors deserve special attention in the elderly age group. Shock¹⁰ has shown in a study of elderly men that inulin clearance, a measure of glomerular filtration, is 60 per cent of normal, whereas Diodrast clearance, which gives a more complete over-all picture of kidney function, is decreased to 45 per cent of normal. The recent work of Trueta et al.¹¹ in demonstrating the renal shunt mechanism following fractures of extremities and other noxious stimuli makes it evident that trauma, with its concomitant shock, may further decrease renal function to the point of serious decompensation. We have found that operation on a patient with an elevated or rising nonprotein nitrogen can have disastrous results. Of similar importance is the carbon dioxide combining power of the blood. One of the prime functions of the kidney is the regulation of the acid-base equilibrium of the body. It does this by a process of selective retention or excretion of various salts. An early manifestation of impaired function is often a loss of this fine discriminatory power. As a result there is a retention in the body of sulfates and phosphates at the same time that there is a loss of fixed base. This can lead to a rather severe acidosis which must be corrected prior to operation. If the nonprotein nitrogen is high or the carbon dioxide low

the condition is corrected preoperatively by the use of fluids, sodium lactate or bicarbonate and saline solution as indicated. If there is no chemical improvement or still further deterioration, operation should not be performed.

Renal-tract infection was seen in 10 of the 72 patients operated on either before or after surgery. It is important to maintain an adequate urine flow both in the prevention and in the treatment of this condition. In men urinary retention secondary to prostatic obstruction must be avoided and constant drainage should be instituted whenever there are signs and symptoms of such a difficulty.

Complete studies on water and electrolyte balance have been presented by Maddock and Coller.^{12, 13} Sufficient fluid should be administered either by mouth or parenterally to maintain a urine output of 1000 to 1500 cc daily.

Diabetes Mellitus

ACUTE HERPETIC GINGIVOSTOMATITIS IN THE ADULT*

ARTHUR M. ROGERS, M.D.,† LEWIS L. CORIELL, PH.D., M.D.,‡ HARVEY BLANK, M.D.,§ AND THOMAS F. MCNAIR SCOTT, M.D.¶

PHILADELPHIA

THE majority of people, about 70 per cent, experience their first infection with the herpes simplex virus in infancy or early childhood. This infection is usually inapparent, and can therefore only be recognized as having occurred by the presence of circulating antibodies.¹ However, in about 1 per cent of all infections, the first attack of the virus can give rise to a serious or even fatal disease. These primary infections, of which the commonest is the clinical entity known as acute herpetic gingivostomatitis,²⁻⁶ are well recognized in childhood because they commonly occur in this age group. In adult life, however, these clinical manifestations, on the basis of the figures just quoted, rarely occur and therefore are liable to go unrecognized as herpetic infections. The common adult manifestation of infection is recurrent herpes labialis or "fever blisters." These recurrent attacks are usually accepted as being due to a reactivation, by non-specific stimuli, of the herpes virus that has lain latent in the tissues of the host since recovery from the primary infection, whether clinical or inapparent.

In view of these facts, it seems worth while to record the clinical picture of primary herpetic infection that occurred in 3 adult patients.

Youmans,⁷ in 1932, reported the first case in an adult in which the virus was isolated. Long⁸ described 3 cases with the isolation of the virus from two. Scott, Steigman and Convey⁹ observed a primary infection in a mother whose children were being treated for the same disease, in addition to isolating the virus, the authors demonstrated the development of neutralizing antibodies during convalescence. Scott¹⁰ discussed another case in a soldier in England from whom the virus was isolated, and the development of antibodies was demonstrated during convalescence. Ziskin and Holden¹¹ reported 8 cases of acute herpetic gingivostomatitis

in adults, and Florman and Trader¹² a case in an adult. In all these cases the clinical impression was corroborated by laboratory findings.

CASE REPORTS

CASE 1. A 21-year-old secretary was admitted to the Hospital of the University of Pennsylvania on December 3, 1947, complaining of sore mouth and fever. Her illness had begun 2 days previously, when she had discovered, on brushing her teeth, that the gums were extremely painful. She felt a little nauseated. For the next 2 days she felt chilly and feverish, and her gums became progressively worse. A slight headache developed, but there was no stiffness of the neck.

The patient had never previously had a cold sore or "canker sores." Her mother had typical herpes labialis at the onset of the patient's illness.

Since the patient was later found to have infectious mononucleosis, in addition to the herpes simplex infection, some further details about two febrile illnesses that occurred in the month preceding the onset of the present illness are presented. On November 1 a running nose, sore throat, and backache developed, and the patient was sick, with a fever, for 4 days. Her temperature reached a maximum of 102°F. She recovered and returned to work until November 14, when a sore throat and fever of 4 days' duration occurred, the temperature rose to a maximum of 102°F. During this illness, she was under the care of her family physician, who made a diagnosis of acute tonsillitis and treated her with sulfadiazine. When seen by one of us (A. M. R.) in consultation on November 17, she had a temperature of 100°F, and was feeling much better than she had for the previous 2 days. Her pharynx was moderately inflamed, and both tonsils were enlarged and partially covered with a gray-white exudate. No blood counts or other laboratory studies were done at this time. She recovered from this illness and returned to work on November 24, working regularly until the day of admission.

Physical examination revealed that the breath was foul, the gums were swollen and inflamed, especially along the gingival margins, and bled easily on manipulation, inside the lower lip at the angle of the mouth were two aphthous ulcers, and many unruptured small blebs were scattered throughout the buccal mucosa. On the left buccal mucosa there was a white, desquamating patch, 1 cm. in diameter. The submaxillary and posterior cervical lymph nodes were enlarged and tender. No other lymph nodes were enlarged. The spleen was not palpable.

The temperature was 103.4°F.

Examination of the blood showed a hemoglobin of 81 per cent and a white-cell count of 6100, with 53 per cent neutrophils, 21 per cent monocytes, 24 per cent lymphocytes, 1 per cent eosinophils and 1 per cent basophils. No immature cells were seen. On December 6 an essentially similar count was obtained except that a few immature atypical lymphocytes were noted. Urinalysis on three occasions was negative. A gingival smear for Vincent's organisms taken on the day of admission was negative, and a throat culture revealed a normal flora. Blood drawn for heterophil-antibody tests on December 6 revealed a titer of 1:5096, which was reduced to 1:448 after absorption with guinea-pig antigen, and was completely absorbed by beef-cell antigen.

*From The Children's Hospital and the departments of Medicine, Pediatrics and Dermatology of the University of Pennsylvania School of Medicine.

§Fellow in the medical sciences, National Research Council.

¶Research professor of pediatrics, University of Pennsylvania School of Medicine; director of research and clinics, Children's Hospital.

The mouth lesions increased in severity, and on December 6, 51 distinct aphthous ulcers were counted on the uvula, tongue, buccal mucosa, gingiva and hard palate. They were equally distributed on both sides. Enlarged and tender submental lymph nodes were noted at this time. The temperature became normal on the 8th day of illness, and the patient was discharged to her home. She reported on December 11 that she had only three unhealed lesions. When she was seen on December 15 no lymphadenopathy was present, and the oral mucous membranes were normal except for a slight redness along the gingival margins, which had disappeared by December 29.

In February, 1948, the patient complained of painful, bleeding gums for a week. In March an aphthous ulcer appeared on the buccal mucosa, but the virus of herpes simplex could not be isolated at this time, and a biopsy of the ulcer showed no typical inclusion bodies. Since then the patient has had no trouble with her mouth.

The diagnosis of herpetic stomatitis was confirmed by three methods: isolation of the virus of herpes simplex from the oral lesions, biopsy of one of the mouth lesions, and demonstration of neutralizing antibodies in the convalescent serum that were absent in the serum taken at the onset of the disease.

On December 4, 1947, saliva was collected and, after treatment with penicillin and streptomycin, was inoculated onto the chorioallantoic membrane of embryonated hens' eggs. Subsequent examination of the membrane showed numerous plaques similar to those produced by the virus of herpes simplex. The virus was propagated serially in eggs, and was specifically neutralized by rabbit antiserum for the HF strain of herpes simplex virus. Biopsy of one of the ulcers of the patient's mouth was taken on December 4, 1947. In the microscopical section stained with hematoxylin and eosin, balloon-

FIGURE 1 Biopsy of Aphthous Ulcer of the Buccal Mucosa in Case 1

Three swollen epithelial cells containing herpetic inclusion bodies that completely fill the nucleus are surrounded by an inflammatory exudate (hematoxylin and eosin stain $\times 300$)

ing cells containing intranuclear inclusion bodies typical of herpes simplex infection were seen in the epidermis (Fig 1). Neutralization tests were carried out on the egg membranes with the HF strain of herpes-simplex virus and the patient's acute and convalescent serums. No neutralizing antibodies were present in the serum drawn on December 4, whereas the 1:16 dilution of serum drawn on December 15 completely neutralized the standard strain of herpes simplex virus.

CASE 2 E. C., a 34-year-old housewife, was seen at home on September 20, 1947, with the chief complaint of "sore mouth," headache, backache and malaise of 1 day's duration. She dated the onset of the sore mouth and gums from the previous day, when she had massaged her teeth and gums vigorously. She had never had a cold sore in her life, although her husband had frequent cold sores and was recovering from a recent attack at the time.

Physical examination showed the anterior cervical lymph nodes to be swollen and tender, the gums were slightly

swollen and red, especially along the gingival margin. On the following day the temperature was 100°F, the gums were more swollen and more inflamed, and several aphthous ulcers were seen inside the lower lip, on the tongue and on the gingiva. Several grouped vesicles were seen on the lips at the left angle of the mouth. The malaise, fever and sore mouth persisted for 1 week. On September 30, a few healing ulcers were still visible on the gingiva and lips, although there was no subjective pain at this time.

The temperature by mouth was 99.1°F.

Gingival smears were made for Vincent's organisms on September 21, 26 and 30, all were negative. A culture of the gingiva on September 21 revealed no abnormal bacteria. From saliva collected on September 23, herpes-simplex virus was isolated in chick embryos. Serums taken during the acute and convalescent stage of the disease showed a rise in titer of neutralizing antibodies for herpes simplex from 0 to 1:16.

CASE 3 A 1st-year medical student noted the onset of his illness on April 22, 1948, when the submental and submaxillary lymph nodes became tender and swollen. On the following day, the gums were sore, and he began to feel chilly and feverish intermittently. For the next 4 days the soreness

FIGURE 2 Appearance of the Mouth in Case 3 on the Sixth Day of the Disease, Showing Five Aphthous Ulcers of the Mucous Membrane and One of the Iermilion Border

The gingivae are red and swollen

of the gums progressed and involved the cheeks, tongue and throat. He was admitted to the Student Health Service of the University of Pennsylvania with an oral temperature of 100°F and a pulse of 90.

Physical examination revealed a moderate bilateral cervical adenopathy, with ulcerations on the lips, buccal mucosa, tongue and tonsils (Fig 2). A palpable lymph node was felt in the left axilla. No other nodes were enlarged. The spleen was not felt.

The urine was normal. Examination of the blood disclosed a white-cell count of 8000, with 71 per cent neutrophils, 26 per cent lymphocytes and 3 per cent monocytes. The temperature rose to a maximum of 100.6°F, and then gradually subsided over the next 4 days, reaching normal on the 9th day of the disease. The mouth lesions continued to progress and became worse until the 8th day of the disease. From then on, the healing was quite rapid. On April 28 a heterophil-antibody test was negative, as was a serologic test for syphilis. Neutralizing antibodies against the herpes-simplex virus were absent from the serum taken on the 7th day of the disease, but present in serum drawn 2 weeks later.

DISCUSSION

The clinical features of the 3 cases presented are similar to those previously reported in both children

and adults. No patient gave a history of previous fever blisters or canker sores, and in 2 cases recent contact with a person who had a cold sore suggested a likely source of infection. The chief complaint of the 3 patients was sore mouth, fever and malaise. Inspection of the oral cavity revealed in some cases vesicular lesions, but chiefly many small, shallow discrete ulcers measuring 1 to 5 mm in diameter. The gingivae were acutely inflamed along the margin. Ulcerations were frequently present on the alveolar and palatal gingivae. The regional lymph nodes were uniformly enlarged. The temperature varied from 100 to 103°F by mouth, returning to normal during the course of a week. New lesions kept appearing in the mouth during the first few days, and remained painful throughout the first week. Healing gradually occurred during the second week, without scarring.

In the 2 cases so examined, the total white-cell count was not elevated. Except in the patient who was recovering from infectious mononucleosis, the differential counts were normal. In the 3 cases reported by Long,⁸ the white-cell and differential counts were within normal limits.

The diagnosis of infection with herpes-simplex virus was confirmed in each case by the demonstration of the development of specific neutralizing antibodies during convalescence. In 2 cases the herpes-simplex virus was recovered from saliva, and typical inclusion bodies were seen in sections of biopsy material in 1.

The sudden onset of fever, sore mouth and regional adenopathy in a previously healthy adult immediately presents a problem of differential diagnosis. The diagnostic probabilities include Vincent's infection, or trench mouth, erythema multiforme, infectious mononucleosis, syphilis, agranulocytosis, acute leukemia, pemphigus vulgaris and diphtheria of the pharyngeal or tonsillar region.

A negative peridental smear for organisms of the Plaut-Vincent type is helpful, but a positive smear is of no value because these organisms are frequent in normal mouths, and more frequent in the presence of acute inflammation when pain prevents proper cleansing and oral hygiene. Burket¹³ and Ziskin and Holden¹¹ stress ulceration of the interdental papilla as the typical lesion of acute Vincent's infection, and in severe cases they describe ulcerations covered by a gray or yellow pseudomembrane on the palatal, buccal and labial mucosa. The fusospirochetal infection can be controlled by penicillin therapy, which does not shorten the course of the herpetic gingivostomatitis.

The treatment is symptomatic. The use of tetracaine hydrochloride 1 per cent (Pontocaine Hydrochloride) or p-amino-benzoyl-dibutyl-amino-propanol sulfate 2 per cent (Butyn Sulfate) locally before meals affords much comfort. The intense soreness of the gums makes brushing of the teeth impossible, so that irrigation of the mouth is essential.

We have used benzalkonium chloride 1-1000 (Zephiran) or cetylpyridinium chloride 1-4000 (Ceepryn) for that purpose. Penicillin should be used to control secondary infection by fusospirochetal organisms or pyogenic cocci.

Recurrent fever blisters are generally accepted to be manifestations of a recrudescence of a latent herpes-simplex virus, but there is no laboratory evidence that recurrent aphthous ulcers are caused by this virus. It is interesting to note that one of the patients did have a "canker sore" for the first time in her life after recovery from the primary infection. However, no herpes virus was recovered, nor were the inclusion bodies seen in a biopsy specimen of this lesion.

Levine et al.¹⁴ reported, as probably herpetic in origin, an epidemic of vesicular pharyngitis and stomatitis that involved almost 50 per cent of 230 people in a summer camp. Recent knowledge of the epidemiology and clinical manifestations of herpes indicates that this epidemic was not due to infection with the virus of herpes simplex for the following reasons: most people over three to five years of age have already contracted a primary infection and are immune to reinfection from without, vesicles, rarely observed in herpetic gingivostomatitis, were "present in all the epidemic cases", the ulcers were "grayish yellow," in contrast to the whitish ulcers of herpes, and some of the most consistent findings in herpes infection—marginal gingivitis, pain and regional lymphadenopathy—were minimal or present in less than half the epidemic cases. We have observed a small epidemic of the syndrome described by Levine et al. and were unable to isolate a virus or to demonstrate a rise in neutralizing antibodies for herpes simplex during convalescence.

SUMMARY

Three cases of acute herpetic gingivostomatitis in adults are reported. The clinical picture is described, and its similarity to the disease in infants is noted—namely, an acute, febrile illness with malaise, chilliness, multiple aphthous ulcers of the mouth and pharynx, marginal gingivitis and regional-lymph-node enlargement.

The methods by which a positive diagnosis may be established in the laboratory are illustrated: isolation of the virus, demonstration of typical inclusion bodies in a biopsy specimen, and the appearance of specific neutralizing antibodies in the serum during convalescence.

RADIATION EXPOSURES FROM THE USE OF SHOE-FITTING FLUOROSCOPES

CHARLES R WILLIAMS PH D *

BOSTON

IT IS now common practice in many shoe stores and shoe departments of department stores to supplement usual shoe-fitting methods by the use of fluoroscopes known as x-ray shoe fitters. Because this technic has spread rapidly throughout the United States, particularly in stores specializing in children's shoes, it is desirable to know precisely the exposures to irradiation received by customers as well as by clerks and other persons in the area of x-ray shoe-fitting units.

For this reason a series of studies was undertaken for the purpose of measuring foot dosage, leakage through the walls of the cabinet and scattering from the opening in which the customer places his feet. The data obtained form the basis of this report.

EQUIPMENT

The unit consists essentially of a 50-kv x-ray tube operating at 3 to 8 milliamperes through a 1-mm aluminum filter, housed in a case lined with lead or steel and containing a fluorescent screen. The focal spot to skin distance is 7.5 to 20 cm. The unit is equipped with an opening for the customer's feet and three viewing openings through which the customer, clerk and one other person can observe the screen. A push-button automatic timer, which can be set for any predetermined time, is included on most installations. In actual use exposure times have been found to vary from five to forty-five seconds although twenty seconds appears to be the most popular setting. *Repeated exposures can be made by releasing and pushing of the button.* More recent models are equipped with three separate switches providing three different intensities — one for men, one for women and one for children.

FOOT DOSAGE

The amount of radiation delivered to the feet of the customer is a quantitative matter related to tube output, focal skin distances and time of exposure. A large series of measurements (on 12 units) using a Victoreen r-meter placed inside a shoe

showed wide variations in the quantity of radiation delivered to the feet.

Figure 1 shows dosage curves for several typical units. Total exposure values were determined for a series of time settings on each shoe-fitter. By the plotting of total r against time the results establish a straight line from which dosage rate can

FIGURE 1 Foot Dosage in Shoe-Fitting Fluoroscope
The timer is normally set for twenty to twenty-two seconds

be derived. All installations tested fall within the range of the curves shown — that is from 0.5 to 5.8 r per second. By multiplying total exposure time and dosage rate, one can determine the total foot dose per exposure. Thus for a twenty-second exposure (that most commonly used) doses ranging from 10 to 116 r could be delivered to the feet of a customer. Repeated fittings increase the exposure in proportion to time.

SCATTERED RADIATION

This is defined in the American Standards Association Code (Paragraph 3-2.1.3)¹ as "radiation which during passage through a substance has been deviated in direction and also may have been modified by an increase in wavelength." The foot opening in shoe-fitting units is the most important source of radiation of this type. After passing

*Assistant professor of industrial hygiene, Harvard School of Public Health.

through the aluminum filter and the customer's feet it escapes from the cabinet through the opening. In most installations this amounts to more than 100 milliroentgens (mr) per hour at 10 feet from the unit and 15 mr per hour at 25 feet. The zone of scattered radiation in excess of 15 mr per hour covers an area of about 90° from the foot opening out into the room.

Figure 2 shows a typical setup in a shoe store. It should be noted that at many of the seats where customers are given preliminary fittings, an area in which clerks may be working, a total daily dose

FIGURE 2 Distribution of Scattered Radiation from Shoe-Fitting Fluoroscope

could be received in one hour of operation by anyone in the area.

CABINET-WALL LEAKAGE

Measurements of leakage directly through the walls of the cabinets showed wide differences between units. These differences varied with manufacturer, age and condition of the equipment and condition of the x-ray tube.

Values were obtained using two rate meters — a Zeus survey meter with a range of 0 to 2500 mr per hour and a Victoreen radiation meter having a range of 0 to 20 mr per minute (0 to 120 mr per hour). Readings were taken at the sides, front, back and in the zone where viewing is done. The front of the machine is the side on which the control buttons are located, the back is where the customer stands. It should be noted that values found on the back are influenced by scattering from the opening where the feet are placed.

It can be seen from Table 1 that there is some leakage directly through the walls of the cabinets.

The figures represent the dosage rates received by persons adjacent to the cabinet. They can be evaluated in terms of the permissible daily dose of 100 milliroentgens (12 mr per hour) as established by the American Standards Association.¹ The length of time for which a person can be in close proximity to one of these units can be determined by comparison of the leakage (rate) with the permissible

TABLE 1 Leakage through Walls of Shoe-Fitting Fluoroscope*

SITE OF LEAKAGE	NO. OF UNITS	AMOUNT OF LEAKAGE		
		BOTTOM mr/hr	MIDDLE mr/hr	TOP mr/hr
Front	12	3 to 6	12 to 48	12 to 36
Sides	12	7 to 60	12 to 36	8 to 24
Back	12	200	30 to 100	6 to 54
Viewing position	12	Values range from 0 to 24 mr per hr		

*Taken at the walls

daily dose. The leakage must be measured for each unit.

CONTROL OF EXPOSURE

There are many steps that should always be taken in the use of this equipment to minimize exposures to customers and clerks. Each unit must be treated as an individual problem.

Foot dosage. The control of foot dosage depends on four factors: the output of the tube, thickness and condition of filters, distance, time of exposure and number of exposures. The control of the first two rests with the manufacturer, and that of the last two with the store.

The American Standards Association¹ and the New York City Health Department² have specified that "The maximum permissible dose per exposure shall not exceed 2 roentgens." New York City requires further that "There shall not be more than 3 exposures in one day and not more than a total of 12 exposures in one year." The only attempt to enforce this provision is a requirement for posting of signs on the machines stating "REPEATED EXPOSURES TO X-RAYS MAY BE HARMFUL. FLUOROSCOPIC EXAMINATIONS FOR SHOE FITTING SHOULD BE LIMITED TO NO MORE THAN 12 IN ONE YEAR." These signs should measure at least 7½ inches by 4½ inches and should be posted conspicuously.

More recent proposals by the Bureau of Industrial Hygiene, Detroit Department of Health,³ require that maximum intensity in the beam shall not exceed 12 mr per minute and that maximum time of exposure shall not exceed five seconds. The same dose limit is being recommended by the Division of Occupational Hygiene of the Massachusetts Department of Labor and Industries. Based on this figure, suggested warning signs state that the

limit for each customer shall be 3 x-ray shoe fittings per day and no more than 12 fittings per year.

These figures indicate the exposure levels now being established by municipal and state authorities in their regulations to control the use of shoe-fitting fluoroscopes.

Scattered radiation and wall leakage. Leakage through the walls of the equipment can be controlled only by the manufacturers, since it depends on shielding in the cabinet and the tube output.

Control of scattered radiation is the responsibility of the user because the controlling factor is the position of the unit with respect to occupied areas.

The New York City Sanitary Code (Section 107a) specifies under Regulation 2 that — "The equipment shall be so constructed that the dosage rate in any region which may be occupied by operators and attendants does not exceed 12.5 milliroentgens per hour." It is obvious from the data shown in

the section on scattered radiation that the back (customer's) side of these units should never be directed toward occupied areas within a radius of 25 feet.

SUMMARY

Measurements on shoe-fitting fluoroscopes in use show that foot dosages may range from 0.5 to 5.8 r per second (time of exposure five to forty-five seconds), that wall leakage may range from 3 to 60 mr per hour and that scattered radiation amounts to more than 100 mr per hour at distances up to 10 feet from the unit.

POTENTIAL DANGERS IN THE UNCONTROLLED USE OF SHOE-FITTING FLUOROSCOPES*

L. H. HEMPELMANN, M.D.

BOSTON

THREE types of radiation injuries may result from the uncontrolled use of low-voltage x-ray machines in shoe stores in the manner described by Dr. Williams in the preceding article. The most likely injuries are interference with normal foot development of children who are fluoroscoped repeatedly when being fitted with new shoes, acute radiation burns of the customer's feet resulting in late permanent skin damage, chronic radiation injury of the blood-forming tissue of store employees who work with improperly shielded x-ray machines. Little is known concerning possible effects of this type of radiation on the sex glands. Some of the unusual features of these injuries will be discussed, and the possibility of their being caused by existing shoe-fitting fluoroscopes will be considered.

POSSIBLE TYPES OF INJURY

Interference with Foot Development

Growing bone, in contrast to adult bone and hyaline cartilage, is easily damaged by exposure to x-rays. This is due to the radiosensitivity of the epiphyseal cartilage. Damage to this tissue is manifested by reduction in the rate of bone growth and by premature closure of the epiphyseal junction. Experimental studies in animals of the action of x-rays on the epiphyses bring out certain

facts that are related to the present problem. It has been shown that the younger the animal, the greater the effect on bone growth of a given dose of x-rays.¹ In addition, stunting of bone growth in animals can be produced by less than half the dose of 200 kv that will cause erythema of the overlying skin. It has also been demonstrated that fractionation of the dose and prolongation of the intervals between exposure lessen the effect of the radiation on epiphyseal cartilage as well as on other tissue.²

Clinical reports describe cases of cessation of bone development in children who receive radiation therapy for lesions in the region of the epiphyses.³ Therapeutic use has been made of the growth-stunting property of x-rays to minimize inequality in limb length caused by osteomyelitis or other types of bone disease.³ The minimal stunting dose of x-rays has been stated to be a quarter of the erythema dose for infants and half the erythema dose in older children.⁴ If this statement is correct, a few hundred of moderately hard x-rays administered in a single exposure will cause a disturbance in foot development in young children.

Aside from the fact that the epiphyses are extremely radiosensitive, the most important lesson to be learned from clinical experience and from animal experimentation is that abnormal bone development can be produced insidiously in the absence of skin damage or other external evidence of radiation injury. Before the other types of radiation damage are considered it should be stated

*From the Medical Laboratories, Collis P. Huntington Memorial Hospital.

This is publication No. 672 of the Harvard Cancer Commission.

†Special assistant to the director of the Division of Biology and Medicine, United States Atomic Energy Commission; consultant in biophysics, Massachusetts General Hospital; research associate, Harvard Medical School.

that the dosages mentioned in the literature usually refer to more penetrating radiation than that delivered by shoe-fitting fluoroscopes. Consequently, the dose of soft x-rays necessary to damage epiphyseal tissue lying 1 or 2 cm below the skin surface would be more nearly equal to the erythema dose.

Radiation Burns of the Skin

The acute and chronic types of x-ray reactions of the skin are so well known that they need not be described. Innumerable cases of such injuries have been reported in the last fifty years, and yet the data concerning the radiation dosages that cause skin damage, except for that delivered as an acute exposure, are almost nonexistent. At least 600 to 1000 r of soft x-rays given within a day or two would be required to produce a serious skin reaction. If the radiation dosage were fractionated, higher total doses would be necessary to produce comparable skin damage. Little is known of the radiation dosages that cause chronic skin damage. It has been suggested that repeated exposure of the hands to $\frac{1}{4}$ r of gamma rays per week over a period of many years may produce injury.⁵ There is no published information bearing on the maximum radiation dosage that can be administered to the skin with safety at the intervals at which children are likely to be fitted for new shoes (two to four months).

Chronic Radiation Damage of the Blood-Forming Tissues of Store Employees

The hazards involved in repeated exposure of the body to soft x-rays are similar to those encountered in any hospital or physics laboratory that uses x-ray machines or radioactive material. The dangers to blood-forming tissues of chronic overexposure of the body to x-rays are familiar to everyone. Recent experiments illustrate how irradiation with small daily doses of x-rays reduces the life span of animals.⁶ The maximum permissible dose of radiation to which persons can be safely exposed throughout their working lives has been considered for many years to be 0.1 r per day. Within the past few months, however, the Advisory Committee on X-Rays and Radium⁷ has reconsidered this dose and recommended that it be lowered to 0.3 r per week.

DISCUSSION

Consideration of the radiation dosages measured by Dr. Williams, in the light of the biologic information presented, suggests that injury to either the epiphyseal cartilage or the skin is unlikely after a single exposure to the shoe-fitting fluoroscope except under the most undesirable conditions. Several fittings within a day or two may conceivably lead to epiphyseal damage in children or to skin damage in children or adults. Repeated fluoroscopy of the foot by improperly regulated machines

from early childhood to the age of normal closure of the epiphyses (eighteen to twenty years) could result in foot deformities and even in permanent skin damage.

To prevent injury to customers and employees, it is obvious that the use of x-ray machines in shoe stores must be controlled. Proper shielding of the fluoroscope to minimize radiation leakage, education of the users and store officials about the dangers involved in misuse of the machines and reduction of the foot dosage per viewing must be accomplished. Shielding of a low-voltage fluoroscope is a relatively simple matter. Conspicuous warning signs on each machine can help to educate the public to the dangers of too frequent use of fluoroscopy, restriction of the use of x-ray machines to qualified personnel will reduce the possibility of accidental overexposure. Reduction of the foot dosage per exposure can be accomplished by lowering of the tube output, by adequate filtration and by limitation of the exposure by automatic timing devices. Since the maximum amount of radiation that the foot can tolerate at intervals of several months is not known, it seems advisable to reduce the foot dosage to the minimum that is compatible with satisfactory use of the fluoroscope. As Dr. Williams has indicated, the foot can be visualized adequately in a fluoroscope that delivers 1 r in a five-second exposure. Therefore, the newly issued recommendations of the Massachusetts Department of Hygiene (1 r per viewing, three exposures per day and twelve exposures per year) seem to be preferable to the higher dosages permitted by the American Standards Association and the New York City Health Department regulations quoted in the preceding article.

SUMMARY

It may be said that the type of radiation injury most likely to result from the unsupervised use of low-voltage fluoroscopes in shoe stores is the malformation of the feet of growing children. Such deformities may occur in the absence of x-ray reactions of the skin. Skin damage of the feet of customers and injury of the blood-forming tissues of store employees are possible consequences of the misuses of the shoe-fitting fluoroscopes. These dangers can be controlled by proper regulation of the use of the machines.

MEDICAL PROGRESS

GASTROINTESTINAL ALLERGY (Concluded)*

FRANZ J INGELFINGER, MD;† FRANCIS C LOWELL, MD,† AND WILLIAM FRANKLIN, MD‡

BOSTON

LABORATORY TESTS

In patients suspected of gastrointestinal allergy demonstration of the allergic response has at times been sought by radiologic studies. For the most part, the patient has first been examined by means of a barium-in-water meal, followed in a few days by a similar examination, a suspected food being given with or a few hours after the barium suspension. In patients so examined, whether adults or children, the most common finding at the second test was delayed gastric emptying, usually interpreted as indicating allergic pyloric spasm or edema.^{31 40 63 64} This interpretation, however, may be questioned on many counts. All foods, particularly those containing fats, may delay gastric evacuation. In normal children, the painstaking studies of Macy et al^{65 66} show that a barium-water meal leaves the stomach in one and eight-tenths to two and eight-tenths (average one and nine-tenths) hours, but that a barium-milk suspension requires one and five-tenths to four and five-tenths (average three and one-tenth) hours to leave the stomach. An adult stomach may evacuate all of a water meal within an hour but only 20 per cent of a milk meal of similar size.⁶⁷

Against this background, the effects of an allegedly allergenic food cannot be differentiated easily from the normal effect of food on gastric emptying. In fact, those who appreciate that foods delay gastric evacuation postulate abnormal mechanisms only if this expected response does not occur. Thus Macy et al⁶⁵ observed that the milk meal emptied more rapidly than the water meal in one case. To explain this phenomenon, they invoked allergy. The same authors,⁶⁶ however, caution that "many factors are interrelated in the determination of the response of the alimentary canal: the method of measurement, the size of the meal ingested, its temperature, consistency, and content, the nutritional state of the individual and the emotional and environmental condition to which the individual is subject at the time."

If gastric evacuation is delayed the interpretation of pylorospasm is made, as pointed out by Fries and Mogil⁶⁸ only by inference. Gastric evacuation is controlled by a number of factors. Of

primary importance is gastric and duodenal motility rather than isolated spasm of the pyloric sphincter.⁶⁸ Hence, to explain retarded emptying of the stomach on this basis is usually incorrect.

The ingestion of an allergen is also credited with changing small-intestinal motility as demonstrated by a barium meal. The changes seen are irregular transport, abnormal luminal caliber and enlarged mucosal folds, the entire picture frequently resembling the so-called "deficiency pattern."⁶⁹ This pattern, however is not at all specific,⁷⁰ and adequate control studies are not available to exclude the likelihood that the observed changes were caused by food given irrespective of the presence of allergy. The ingestion of milk certainly may produce definite changes, either relaxation of intestinal loops or hypertonic segmentation spasm and rapid transport. Whether this so-called "milk-reaction" is allergic in nature is discussed by Golden.⁶⁹ Although he states that "a diagnosis of intestinal allergy cannot be made on the basis of the roentgen examination at the present time," he believes that hypertonicity and rapid transit in the lower small bowel after the ingestion of milk or other foods suggests allergy. To support this contention, he presents a number of carefully documented cases which, if allergic, again illustrate the inconstant characteristics of gastrointestinal allergy. In one case, allergy of the small bowel is demonstrable by a barium-in-water meal, in another, the meal must contain the offending food, in a third the ingestion of one egg is without effect but a second induces disorder of motor function.

The difficulties of studying allergic reactions of the small intestine are shown in the objective and carefully evaluated work of Wing and Smith.⁷¹ Of 9 patients studied after exposure to a supposedly allergenic food, 7 showed some variation in small-bowel pattern but in only 3 was the change sufficient to exclude, in the authors' opinion a non-specific reaction, and 1 of these suffered from mild ulcerative colitis. The same authors observed no change in the intestinal pattern of sensitized guinea pigs when the antigen was fed. Intravenous injection of the antigen produced anaphylaxis but no significant effect on the radiologic appearance of the small intestine.

X-ray study of the colon exposed to allergens has been fragmentary. In 17 patients given allergen-containing barium enemas, Fries and Mogil⁶⁸ de-

*From the Robert Dawson Evans Memorial Massachusetts Memorial Hospitals and the Department of Medicine Boston University School of Medicine.

†Associate professor of medicine Boston University School of Medicine.
‡Assistant in medicine Boston University School of Medicine.

tected signs of irritability, such as spasms and local constrictions

In summary, radiologic study of the gastrointestinal tract occasionally reveals such marked derangements of appearance and motility after the ingestion of a food that a causal relation between the food and the observed reaction may be assumed, particularly if the x-ray findings are associated with symptoms. The problem is this: How can one be sure that the changes induced are allergic rather than nonspecific? A solution lies in more extensive use of control studies, adequate to exclude nonspecific effects. X-ray evidences of primary intestinal dysfunction are, as Weber⁷² states, "presumably valid when properly controlled. In no field of roentgenologic diagnosis is the exercise of critical judgment and objectivity more necessary, if unwarranted deductions and correlations are to be avoided," and, in referring to the barium enema, "In my opinion the evidence of abnormal physiologic change brought to light with its use is highly unreliable. I hesitate to attach abnormal physiologic significance, for example, to a contracted portion of the sigmoid colon, to a general increase or decrease in the caliber and length of the intestine."

Direct observation of the gastric mucosa by means of the gastroscope should reveal whether this tissue displays transient urticarial edema as may the mucous membranes of the naso-oropharynx. A number of case reports illustrating precisely such a reaction have been collected from the European literature by Schindler.⁷³ Typical is the case of Chevallier,⁷⁴ that of a bee-keeper who, when stung by a bee, fainted, developed generalized urticaria and exhibited symptoms suggesting pyloric obstruction. Gastroscoy performed during one of these episodes revealed transient edema of the antral mucosa. Although the number of such cases is not large and the patients apparently were not seen by Schindler himself, he accepts acute allergic urticaria of the stomach as a rare but definite entity. In this, he receives strong support from the excellent studies of Pollard and Stuart.⁷⁵ These workers used the gastroscope to examine 6 patients before and after ingestion of foods that seemed to produce upper gastrointestinal symptoms. In each case ingestion of the food was followed in thirty to sixty minutes by symptoms, accompanied by changes involving the lower third of the stomach: hyperemia, broadening of the rugal folds, boggy edema, diminution of peristalsis and a lumpy appearance of the mucosa. Seven patients (some with asthma but no gastrointestinal symptoms) were studied as controls. The ingestion of foods in these cases also produced mucosal hyperemia and edema but, in the opinion of the authors, to a much less degree than in the patients with symptoms. Gastrosopic observations tend to strengthen the impression that allergic reactions may occur in the stomach

Skin tests enjoy a varied reputation in the diagnosis of gastrointestinal allergy. The preparation of food extracts for skin testing is complicated by the tendency of certain substances to lose their allergenic activity very rapidly,²³ as well as by the occasional presence in foods of irritants that may produce skin reactions on some basis other than an allergic one. To these difficulties may be added the possibility²³⁻⁴¹ that the allergen in some foods is a product of digestion, and special procedures may then be required for the preparation of suitable extracts.

Most workers have been discouraged with attempts to apply skin tests to the diagnosis of gastrointestinal allergy. Positive skin reactions, though generally regarded as indicating allergic sensitivity of the skin to the substance injected, do not necessarily indicate similar sensitivity of the gastrointestinal tract, nor are negative reactions considered adequate evidence on which to exclude it. These views are based on the absence of correlation between the reaction observed in the skin and the occurrence of gastrointestinal symptoms on exposure of the patient to the substance from which the extract was made.

In attempting to assess the significance of skin reactions in gastrointestinal allergy, we are faced with a further difficulty, which appears to us, for the present at least, to be unsurmountable. As pointed out in this review, the criteria on which a diagnosis of gastrointestinal allergy is usually based leave a good deal to be desired. It is clearly impossible to arrive at a conclusion regarding the value of skin tests in the diagnosis of gastrointestinal allergy until this entity has become better defined.

Variations in the number of leukocytes, eosinophils or thrombocytes following the ingestion of foods have been presented as criteria for making the diagnosis of gastrointestinal allergy.^{29, 58, 64, 76-83} The best known of these tests is the leukopenic index, which was introduced in 1934 by Vaughan⁷⁶ as a means of detecting specific allergens that he believed were responsible for a variety of complaints, such as abdominal pain, urticaria, headache, neuritis, vertigo, asthma, colitis, eczema and indigestion. The usual manner of carrying out this test is as follows: two specimens for white-cell counts are drawn at ten-minute intervals in the fasting state, the test food is then eaten, and counts are done every fifteen minutes for an hour, and a final count is made at an hour and a half. A drop of 1000 cells per cubic millimeter below the mean of the two fasting counts is considered to signify hypersensitivity to the food ingested. The validity of this test is disputed,⁸⁴⁻⁸⁸ and its technic is open to criticism. Loveless et al.⁸⁴ showed that leukocytosis is not the normal response to the ingestion of foods, thus invalidating one of the premises upon which this test is based. Furthermore, postprandial leukopenia occurred with equal rarity

in both food-sensitive and nonsensitive subjects, and the incidence of this leukopenia was that which might result from the random variations that occur in the performance of successive blood counts. Loveless⁵⁴ also demonstrated that the development of asthma, hay fever and urticaria in a small group of ragweed-sensitive patients given ragweed extract subcutaneously was not associated with significant change in the leukocyte level. These findings were confirmed by Brown and Wadsworth,⁵⁵ who found no proof of the existence of either postprandial leukocytosis or an anaphylactic postprandial leukopenia. In spite of this evidence, this test continues to be employed as a means of diagnosing food allergy.⁷⁷⁻⁸² For this reason, it may be emphasized that in the usual technic of counting white cells, the error in duplicate samples may be as much as 20 per cent, and that the coefficient of variation is 10.7 per cent when the total count approximates 7000.⁵⁶ Consequently, the criterion of a reduction of 1000 cells per cubic millimeter that is used in the leukopenic index⁷⁶ would be met in about 1 out of 5 determinations on the basis of random variation alone. Spontaneous fluctuations in the number of circulating leukocytes further impair the significance of a 1000-cell change in the white-cell count.

Similar considerations apply to tests using a rise in eosinophils⁷⁵ or a fall in platelets⁵⁵⁻⁵⁸ as criteria for the diagnosis of an allergic gastrointestinal reaction to foods. Technical difficulties pertain particularly to the enumeration of thrombocytes. The technic of making eosinophil counts is usually not described in the papers employing this method. Hansen,⁵⁷ using a direct counting technic,⁵⁸ believed that a rise of 50 eosinophils per cubic millimeter after the ingestion of a food indicated hypersensitivity. As recent studies have amply demonstrated, however, the number of circulating eosinophils and white cells may be influenced by factors that are unrelated to allergy.⁵⁹

Since Walzer⁶⁰ and Hecht et al.⁶¹ suggest, on the basis of their experimental studies, that gastric acidity inhibits the gastrointestinal reaction to allergenic foods, the question arises whether patients with hypoacidity or anacidity are particularly susceptible to gastrointestinal food allergy. Individual case reports of patients believed to be suffering from such allergy mention gastric hypoacidity as a contributory factor,⁶¹ but abnormalities of gastric secretion have not been observed when groups of patients suspected of having food or other allergies have been studied.⁹²⁻⁹⁴

The presence of eosinophils in fecal mucus has been adduced as evidence favoring the allergic nature of certain diarrheal disorders,⁹⁵ particularly ulcerative colitis.⁶ Bockus,⁴³ on the other hand, writes, "cytologic examination of the stomach, bowel and rectal secretions has given little assistance in determining the etiologic basis of sus-

pected gastro-intestinal allergy." Before the significance of eosinophils in rectal discharges or mucus can be evaluated, further cytologic procedures, such as Bercovitz's⁹⁶ examination of rectal material in various intestinal disorders, appear necessary. Although eosinophilia is frequently associated with the body's reaction to foreign or altered protein, reactions of this type may be the result as well as the cause of a disease. Thus, a necrotic neoplasm may provoke eosinophilia,⁹⁷ and in a similar fashion, eosinophilia in a disease like ulcerative colitis may merely be the result of tissue destruction. If this is true, interpretation of eosinophils in rectal discharges is difficult.

SUMMARY

The experimental production in animals and man of reactions in the gastrointestinal tract due to contact of sensitized tissue with antigen (allergen) appears to be established. Evidence for the spontaneous occurrence of gastrointestinal allergy in man is good but not conclusive. The incidence of such reactions, assuming that they occur, cannot be determined at the present time for a number of reasons: the symptoms of so-called gastrointestinal allergy are common to many conditions and are prevalent in a considerable portion of the population; there are apparently no manifestations peculiar to gastrointestinal allergy alone, and the methods commonly used for diagnosis are not sufficiently accurate. The validity, in particular, of indirect tests, such as skin tests, changes in the number of blood cells or x-ray findings unaccompanied by symptoms cannot be assessed at present. These tests are reliable only to the extent that results can be correlated with proved gastrointestinal allergy, cases of which appear to be exceedingly rare.

Proof that a patient's gastrointestinal symptoms are on an allergic basis theoretically could be achieved if the following requirements were fulfilled: the symptoms should be caused by contact with a specific substance that is innocuous to the bulk of the population, an immune mechanism should be evident in their pathogenesis, and lesions or functional changes in the gut should be demonstrable. These requirements are difficult if not impossible to meet with present knowledge or techniques. However, it seems reasonable to make the diagnosis of gastrointestinal allergy if gastrointestinal symptoms invariably follow contact with a normally inactive substance, and if other causes such as psychic effects and mechanical irritation are excluded. Regarding foods, the following criteria are suggested: the food should be given in capsules by stomach tube or in such a manner that the patient is unaware of its nature, reproducible symptoms, signs or x-ray findings should consistently follow administration of the disguised food at a more or less constant interval possibly not to exceed a

few hours, other foods given to the patient in the same manner should not produce similar changes, and the suspected food given in the same manner to normal subjects should not cause the observed effects.

The fulfillment of these criteria for the diagnosis of gastrointestinal allergy would be a laborious procedure. If the diagnosis could be firmly established in a number of cases, a characteristic clinical pattern might become apparent and correlation with indirect tests might be possible.

BENJAMIN CASTLEMAN, M D, *Associate Editor*

EDITH E PARRIS, *Assistant Editor*

CASE 35351

PRESENTATION OF CASE

A thirteen-year-old boy was admitted to the hospital with the chief complaint of pain in the back and right leg.

Six months before admission the patient fell on the ice and struck his sacrum. For about a week he felt considerable pain, but then was asymptomatic for two months. Four months before entry he noted the sudden onset of a steady dull pain in his right groin associated with a temperature up to 102°F. He was admitted to a community hospital, where an appendectomy was performed. Apparently the appendix was normal. Almost immediately after discharge he complained of right lumbosacral backache, general malaise and nausea. The temperature rose to 102°F and he was readmitted to the hospital. The back pain radiated to the left, and he also complained of pain in and behind the right knee. Since then the pain had been more or less constant and was aggravated by movement and palpation. During this four-month period he noted weakness of the legs. He also had anorexia, weight loss, several episodes of epistaxes and easy bruising of the lips. He had recurrent fever with true chills, and frequent episodes of delirium. The past history was non-contributory.

Physical examination revealed a pale, emaciated boy complaining of pain in the right knee and back. There was no peripheral lymphadenopathy except for small shotty inguinal lymph nodes. The lungs were clear. There was a Grade II systolic murmur along the left sternal border. Examination of the abdomen disclosed tenderness in the left upper quadrant but no definite mass was felt. The liver edge was just palpable, and the spleen was not felt. A fleeting, spherical firm mass was palpable above the left inguinal ligament. Examination of the extremities revealed marked wasting of the legs and atrophy of both quadriceps.

There was tenderness along the sciatic nerve from the great sciatic notch to the calf, and to the right of the third and fourth lumbar vertebrae. The lumbar spine was fixed in slight flexion. The motion of the right hip was extremely painful. The patient walked with a slight limp on the right.

Neurologic examination revealed general weakness of the legs and arms and atrophy of both quadriceps. The deep reflexes were hypoactive. The plantar reflexes were down. Sensation was intact throughout. The eyes were normal except for slight blurring of the disks. There was no nystagmus — horizontal or vertical.

The blood pressure was 110 systolic, 80 diastolic. The temperature was 99°F, the pulse 100, and the respirations 22.

Urinalysis revealed no abnormality. The white-cell count ranged from 7700 to 4000, with a normal differential on admission changing to one in which 9 per cent of peculiar cells called "plasma cells" were found. The hemoglobin was 10.6 gm on admission. There was hypochromia, anisocytosis, poikilocytosis and polychromasia.

A bone-marrow aspiration of the first lumbar vertebra revealed on one of several stained specimens a sheet of abnormal cells that appeared to resemble plasma cells or malignant tumor cells.

The stools were guaiac negative. The total protein was 7.6 gm per 100 cc, with an albumin of 4.7 gm and a globulin of 2.8 gm. The nonprotein nitrogen was 24 mg, the calcium 10.1 mg, the phosphorus 4.9 mg, and the alkaline phosphatase 6.1 units per 100 cc.

The cerebrospinal fluid was normal. An electromyogram showed an abnormal record; there were spontaneous fasciculations in the muscles of the upper extremities.

X-ray examination of the chest and abdomen was negative. X-ray examination of the bones revealed diffuse granularity of all the bones of the lumbar spine and pelvis, suggesting demineralization. An area of destruction was disclosed in the body of the fifth lumbar vertebra and another in the left tenth rib in the axillary line.

The patient ran a low febrile course, with significant progressive weight loss and frequent episodes of lower lumbar pain extending down to the right leg. On several occasions he experienced severe crampy pain radiating from the thoracic spine. The pain was sufficiently severe to require the administration of morphine on several occasions.

On the twenty-fourth hospital day a segment of the tenth left rib was removed.

DIFFERENTIAL DIAGNOSIS

DR CHARLES S KUBIK. I think it should be stated that not only were the knee jerks weak but also there was a marked difference between the right and the left. The right was considerably weaker than the left.

few hours, other foods given to the patient in the same manner should not produce similar changes, and the suspected food given in the same manner to normal subjects should not cause the observed effects

The fulfillment of these criteria for the diagnosis of gastrointestinal allergy would be a laborious procedure. If the diagnosis could be firmly established in a number of cases, a characteristic clinical pattern might become apparent and correlation with indirect tests might be possible.

DR KUBIK This clinical summary does not begin to indicate the difficulties encountered in making the diagnosis. There was a considerable difference of opinion among clinicians and radiologists regarding the significance of the x-ray findings, which now seem so clearly defined. The lesion in the rib was not discovered until after the patient had been in the hospital for some time. He looked very ill, he had lost weight, and nearly every movement resulted in pain, so that the question of generalized tumor involvement had to be most thoroughly investigated.

DR BAUER I wonder, since he had "plasma cells" in the smear, with similar cells having been found in the bone-marrow aspirations, why the surgeons chose to do a resection of the rib to be certain what they were dealing with. With that amount of evidence there must have been some question about the plasma cells, both in the smear and in the marrow.

DR FRANK B. NORBURY They were seen by several people, who were sure they were abnormal cells, and the term "plasma cell" was the most logical one for them. We thought that biopsy would give a more direct answer than aspiration alone.

DR L. S. P. DAVIDSON (Edinburgh) I think the cytology of these cells is important. The patient was suffering from some diffuse malignant process involving many bones. I do not believe the absence of Bence-Jones bodies or changes in the plasma protein rule out multiple myeloma. Fifty per cent of the cases at the time of diagnosis do not have these changes. On the other hand, the findings of anemia, weakness, pain and temperature are frequently noted. It seems to me that because of the malignant process in the bone marrow, the cytology becomes of great importance. I do not believe one should rule out multiple myeloma because certain features are not present. If we accept the finding of "plasma cells," one should consider it seriously. The plasma-cell increase in the peripheral blood — 9 per cent — is interesting, and I have only seen 1 case — that was my first case, twenty-five years ago — in which multiple myeloma was associated with plasma cells in the peripheral blood. We have diagnosed 40 or 50 cases by radiology followed by sternal puncture or, frequently, by sternal puncture alone. I think this patient may well have had multiple myeloma.

DR BENJAMIN CASTLEMAN Have you seen it in a patient this young?

DR DAVIDSON I only see patients from fourteen years of age up, so I would not be able to answer that.

CLINICAL DIAGNOSIS

Neuroblastoma?
Multiple myeloma?

DR. ROSS'S DIAGNOSIS

Neuroblastoma

ANATOMICAL DIAGNOSIS

Neuroblastoma metastatic, of rib

PATHOLOGICAL DISCUSSION

DR CASTLEMAN The rib biopsy demonstrated neuroblastoma — a classic one showing small cells with the characteristic grouping in so-called rosettes. It is interesting to recall that the neuroblastic origin of this tumor was first clearly proved in this building in 1910 by Dr. James Homer Wright,¹ then director of the laboratory, though the possibility of such an origin had been suggested by Marchand² as early as 1891. Until then they were called small-cell sarcoma or lymphoma, and it was Wright who described 5 cases and showed that the tumor cells produced nerve fibrils. Here are some of Dr. Wright's original lantern slides, showing the rosettes very clearly.

DR ROSS Would the finding in the bone marrow fit in with the picture one sees at autopsy?

DR CASTLEMAN I did not see the bone-marrow aspiration, but I think it is quite probable that neuroblasts may have been mistaken for plasma cells. Neuroblasts are pear-shaped cells and the nucleus is characteristically eccentric.

CASE 35352

PRESENTATION OF CASE

A forty-five-year-old housewife entered the hospital complaining of pain in the right lower quadrant.

Six months prior to admission the patient noticed a mass in the lower abdomen, which grew steadily and rapidly until admission. During this period she had three attacks of pain in the right lower quadrant, the first two preceding her menstrual periods. The pain was sharp, moderately severe and nonradiating.

DR RALPH A ROSS In summary, we have a thirteen-year-old boy with an injury to the lower back, who was asymptomatic after a period of a week. Two months later, he had pain in the region of the injury, extending down the right leg, associated with recurrent fever, chills, delirium, anorexia, anemia and a hemorrhagic tendency, with evidence of neurologic difficulty as brought out by Dr Kubik.

Examination showed a basal systolic murmur in the heart, possibly due to the increasing anemia, and evidence of a lesion in the lower lumbar region, with probable involvement of the sciatic nerve on the right, a lesion in the left rib and a possibility of some intracranial or posterior orbital lesion to explain the blurring of the disks.

May we see the x-ray films?

DR STANLEY M WYMAN These films were taken on two different dates. In the first group the chest and heart appear within normal limits. There is definitely a destructive lesion in the left tenth rib as described in the protocol. It seems to be purely osteolytic, with no evidence of bone reaction. This particular film shows no evidence of expansion of the bone.

DR WALTER BAUER How about the ribs on the right?

DR WYMAN I think these are vascular markings that extend across the rib and create a pseudodefekt. I do not believe it is a true lesion in the rib. However, a diffuse granularity is seen throughout all the bones of the lumbar spine, pelvis and upper femur. In the films taken a month later the fifth lumbar vertebra shows a diffuse denseness throughout its entire body, with a suggestion of some irregular destruction of the anterior portion and possibly the lower posterior angle of the body.

DR ROSS Are there any films of the upper extremities?

DR WYMAN There are none available.

DR ROSS The patient had a traumatic injury six months before hospital admission apparently not related to his subsequent illness. However, one might consider that it had initiated the train of events that led to the symptoms bringing him to the hospital. I do not believe that injury would explain the picture we are dealing with.

Could infection have been the main factor in this picture? The systemic symptoms, the malaise and the fever certainly could all be explained on the basis of general infection. He had progressive

anemia. Could the bone lesions, the destructive lesions in the fifth lumbar vertebra and the tenth rib have been on the basis of localized infection? That does not, however, satisfy the description of the generalized granularity — the demineralization of the bones in the pelvis.

So far as neoplasms — localized neoplastic disease, such as Ewing's tumor or osteogenic sarcoma — are concerned, again, the fever, the systemic signs and the central-nervous-system signs would fit primary bone tumor with metastases. However, I think after a period of four months the x-ray diagnosis should have been more definite, and the normal serum phosphatase indicates a destructive lesion without new bone formation, which would be against the diagnosis of primary bone tumor. The widespread involvement of the bone marrow, as evidenced by the leukopenia, the progressive anemia and the hemorrhagic tendency, suggests a neoplasm, primarily involving the medullary tissue.

Hodgkin's disease comes up for consideration — a rare condition in the pediatric age group — in this case appearing largely in the medullary tissue. I do not believe it was Hodgkin's disease.

Multiple myeloma gives a picture of diffuse bone disease. A normal serum protein is against the diagnosis as is the fact that this is a very rare condition in childhood. Aleukemic leukemia would again explain the picture of the widespread medullary disease, the large lesions in the lumbar spine and rib. Vague masses in the abdomen could be explained on the basis of large areas of leukemic infiltration. The finding of "plasma cells" in the pleural fluid and the suggestion of similar cells seen in smears of bone-marrow aspiration make the possibility of a lymphatic leukemia of the plasma cell type a likely one. This disease, although it is rare, is sometimes seen in the pediatric age group as one of the chronic leukemias and may cause findings such as those described.

Another neoplastic disease that I should like to consider is neuroblastoma, the commonest of the bone diseases in children. It involves the retroperitoneal space, the orbits and the intracranial structures and is often evidenced mainly by involvement of the medullary tissue. Because of the statistical probability, I shall leave my diagnosis as neuroblastoma involving mainly the fifth lumbar vertebra and the tenth rib on the left side, with general spread to the medullary tissue.

blood might reach this size if it developed slowly. The elevated prothrombin time suggests that hemorrhage was possible, but such a condition is extremely unlikely. Pelvic inflammatory disease, with an abscess, could cause a tumor of this size, but this is also unlikely since if she had had pelvic inflammation for six months, she surely would have had other symptoms associated with this entity early in the illness. Something new or dramatic happened to this tumor just before this hospitalization, and tubal disease does not fit the picture.

Since we have eliminated the uterus and the tube, the tumor mass must have been in the ovary. When enlargements of the ovary are considered, endometriosis must be mentioned. This would have been an enormous endometrioma, but that is possible. Endometriosis, however, is unlikely in a para IV, since that disease—like fibroids—is usually seen in women who have two or less children. The mass could have been a dermoid cyst, pseudomucinous cyst, fibroma, ovarian cancer or any sort of ovarian tumor. Since we postulate that this mass was a tumor of the ovary, we now have to explain what happened to it to account for the symptoms that brought the patient to the hospital and made her so ill. There are three possible explanations: a twist of the cyst, with infarction, sepsis within a cyst, which occasionally occurs in the dermoid cyst, and hemorrhage into the cyst. The history does not state that the tumor increased markedly in size, but because of the elevated prothrombin time I think a sudden hemorrhage is the best explanation. I will narrow my diagnosis down to an ovarian tumor mass, possibly an endometrioma, with hemorrhage into it, to account for this clinical picture.

DR BENJAMIN CASTLEMAN: Dr Klemperer, would you like to comment?

DR FRIEDRICH W KLEMPERER: I cannot see any relation of the rheumatoid arthritis to the mass. I wonder what medication the patient had. It is

stated in the literature that salicylate medication, which patients with rheumatoid arthritis frequently receive, is sometimes associated with an elevated prothrombin time.

DR WILLIAM BECKMAN: Our problem with this patient was somewhat different from Dr Ingersoll's. She looked sick from the time of admission, and she did have severe chronic rheumatoid arthritis. While she was on the ward, she had a normal temperature for the first forty-eight hours and then began to develop this elevated temperature, which remained elevated. The problem, therefore, was to decide whether the fever was in any way related to the rheumatoid arthritis, which would have made surgery unwise. After a few days, having ruled out to the best of our knowledge any extra-abdominal cause for her fever, operation was performed. The preoperative diagnosis was infarction of a pedunculated fibroid.

CLINICAL DIAGNOSIS

Infarcted pedunculated fibroid

DR INGERSOLL'S DIAGNOSIS

Hemorrhage into ovarian tumor, endometrioma?

ANATOMICAL DIAGNOSIS

Torsion and infarction of ovarian fibroma

PATHOLOGICAL DISCUSSION

DR CASTLEMAN: This patient was operated upon by Dr Howard Ulfelder, who found a large right ovarian tumor that had twisted one and a half times on its pedicle. When received in the laboratory, the tumor measured 20 by 15 by 9 cm and was deep red. The surface was covered with recently thrombosed tortuous veins, and the pedicle, which was 3 cm in diameter, was also a collection of thrombosed vessels. On section the tumor was solid, soft and obviously infarcted. Microscopically it was a benign fibroma.

The third attack occurred on the morning of the day of admission and was similar to the others but considerably more severe. There were no other symptoms. The last menstrual period began eight days before admission and lasted six days, the duration and flow being considered normal. Menses occurred every twenty-eight days and were usually preceded by a slight mucoid discharge. There had been no weight loss, change of bowel habits, menorrhagia or urinary symptoms.

The patient had been married thirteen years and had four children ranging in age from twelve to four years. She had had fairly severe rheumatoid arthritis for the past ten years.

Physical examination revealed a moderately tender mass in the lower abdomen, extending to the level of the umbilicus. It was about the size of a five-months' pregnant uterus, and was only slightly movable. The abdomen was stretched over the mass, and spasm could not be accurately evaluated. Peristalsis was normal. On pelvic examination the cervix was normal. The uterus could not be defined, but the cervix was not fixed. The mass was easily palpable but too large to enter the true pelvis. The vaults contained no other tumors. There was a slight, white, stringy vaginal discharge. The chest and heart were normal.

The temperature was 98.6°F, the pulse 66, and the respirations 16. The blood pressure was 158 systolic, 84 diastolic.

The hemoglobin was 85 per cent, and the white-cell count 18,800. The urine was normal. A barium enema showed the terminal ileum displaced into the right upper quadrant by a mass in the lower abdomen. The colon was normal. An intravenous pyelogram was interpreted as being normal, except for some evidence of pressure on the lower ends of both ureters by a large irregularly outlined, homogeneous mass extending from the pelvis upward. No tumor cells were found by vaginal smear. A rabbit test for pregnancy was negative.

On the third hospital day the temperature rose to 101°F, and the pulse to 100. The prothrombin time was 29 seconds (normal, 19 seconds). The respirations remained normal. The abdominal mass became progressively more tender on each succeeding day. In a chest film taken on the fourth day there was a small linear area of increased density above the right leaf of the diaphragm laterally. The prothrombin time rose to 41 seconds, and the white-cell

count was 20,800. The temperature remained elevated between 100 and 103°F.

An operation was performed on the seventh hospital day.

DIFFERENTIAL DIAGNOSIS

DR FRANCIS M INGERSOLL. In the discussion of this case there are three outstanding things that have to be correlated. First we note that the patient had an obvious tumor mass in the lower abdomen of six months' duration. We do not know what this mass was but will try to make a diagnosis. The second important point is that some change occurred in the mass that caused pain and precipitated hospital admission. The third point is that her hospital course was characterized by fever, leukocytosis and prostration. An elevated prothrombin time was discovered, which may be significant and may help to explain what happened within the mass. The hospital course suggests sepsis, and the possibility of sepsis in the tube, ovary or appendix must be considered and will be discussed later.

I would like to see the x-ray films to discover if they will give any leads in this situation.

DR JAMES R LINGLEY. It is interesting to note that the appendix is well visualized, so that the possibility of acute appendicitis or abscess is well ruled out. The mass extends out of the pelvis up to the level of the second lumbar vertebra, with pressure on the ureters. The ureters are filled down to the level of the mass. On the barium-enema examination the terminal ileum is displaced upward, outlining the upper border of the mass. It states in the protocol that the mass was irregular, but I would say that throughout most of the examination it is fairly smooth and not lobulated.

DR INGERSOLL. The first problem is to try to decide what the mass was, or with which organ it was associated. The possibility that it was in the gastrointestinal tract is unlikely, the gynecologic system is much more probable. A tumor of the uterus of six months' duration would be either a sarcoma or a fibroid. Fibroids of this size rarely occur in women who have had four children, especially when the last pregnancy was only four years previous to the onset of symptoms, as it was in this particular case. The history of normal menses argues against a uterine tumor.

This tumor may have been a pathologic process associated with a fallopian tube. A tube filled with

blood might reach this size if it developed slowly. The elevated prothrombin time suggests that hemorrhage was possible, but such a condition is extremely unlikely. Pelvic inflammatory disease, with an abscess, could cause a tumor of this size, but this is also unlikely since if she had had pelvic inflammation for six months, she surely would have had other symptoms associated with this entity early in the illness. Something new or dramatic happened to this tumor just before this hospitalization, and tubal disease does not fit the picture.

Since we have eliminated the uterus and the tube, the tumor mass must have been in the ovary. When enlargements of the ovary are considered, endometriosis must be mentioned. This would have been an enormous endometrioma, but that is possible. Endometriosis, however, is unlikely in a para IV, since that disease—like fibroids—is usually seen in women who have two or less children. The mass could have been a dermoid cyst, pseudomucinous cyst, fibroma, ovarian cancer or any sort of ovarian tumor. Since we postulate that this mass was a tumor of the ovary, we now have to explain what happened to it to account for the symptoms that brought the patient to the hospital and made her so ill. There are three possible explanations: a twist of the cyst, with infarction, sepsis within a cyst, which occasionally occurs in the dermoid cyst, and hemorrhage into the cyst. The history does not state that the tumor increased markedly in size, but because of the elevated prothrombin time I think a sudden hemorrhage is the best explanation. I will narrow my diagnosis down to an ovarian tumor mass, possibly an endometrioma, with hemorrhage into it, to account for this clinical picture.

DR BENJAMIN CASTLEMAN: Dr Klemperer, would you like to comment?

DR FRIEDRICH W. KLEMPERER: I cannot see any relation of the rheumatoid arthritis to the mass. I wonder what medication the patient had. It is

stated in the literature that salicylate medication, which patients with rheumatoid arthritis frequently receive, is sometimes associated with an elevated prothrombin time.

DR WILLIAM BECKMAN: Our problem with this patient was somewhat different from Dr Ingersoll's. She looked sick from the time of admission, and she did have severe chronic rheumatoid arthritis. While she was on the ward she had a normal temperature for the first forty-eight hours and then began to develop this elevated temperature, which remained elevated. The problem, therefore, was to decide whether the fever was in any way related to the rheumatoid arthritis, which would have made surgery unwise. After a few days, having ruled out to the best of our knowledge any extra-abdominal cause for her fever, operation was performed. The preoperative diagnosis was infarction of a pedunculated fibroid.

CLINICAL DIAGNOSIS

Infarcted pedunculated fibroid

DR INGERSOLL'S DIAGNOSIS

Hemorrhage into ovarian tumor, endometrioma?

ANATOMICAL DIAGNOSIS

Torsion and infarction of ovarian fibroma

PATHOLOGICAL DISCUSSION

DR CASTLEMAN: This patient was operated upon by Dr Howard Ulfelder, who found a large right ovarian tumor that had twisted one and a half times on its pedicle. When received in the laboratory, the tumor measured 20 by 15 by 9 cm and was deep red. The surface was covered with recently thrombosed tortuous veins, and the pedicle, which was 3 cm in diameter, was also a collection of thrombosed vessels. On section the tumor was solid soft and obviously infarcted. Microscopically it was a benign fibroma.

A LOGICAL PROPOSAL

THE Committee on Membership of the Massachusetts Medical Society has approved and will recommend to the Council a change in Chapter V, Section 2 (b) of the by-laws. As at present worded the section reads

(b) The secretary of a district society shall receive an application from a graduate of a discontinued medical school, a foreign medical school or any medical school not approved by the Council only when

The applicant has possessed a license to practice medicine in the United States or its territories for at least five years

The proposed change applies to the second paragraph, which would subsequently read

The applicant has possessed a license to practice medicine in the Commonwealth, and has conducted that practice in the district from which he makes application, for at least one year

The reasons for such a change are apparent and seem logical. There are now no unapproved schools in existence in the United States, the period of great influx of graduates of foreign schools is over and, in fact, the recent graduates of most foreign schools are not now permitted even to take the examination for registration in Massachusetts. This condition will probably prevail at least until the Council on Medical Education and Hospitals of the American Medical Association has had made the investigation that it is sponsoring of foreign schools and issued its report.

Observation of a physician by his local colleagues for a year is of much greater value as a criterion than any number of probationary years elsewhere.

A five-year probationary period entails an unusual hardship on a physician who, because of lack of society membership, is debarred from staff privileges in many hospitals. It defeats the purpose of the Gallupe Plan, under which graduates of foreign or unaccepted schools are accorded supervised staff privileges. It defeats, indeed, the very purpose of medical organization, which is to ensure the delivery of the best medical care available to the greatest number of persons possible.

A COMMON RADIATION HAZARD

IN THIS era of rapid scientific and technological advances and their practical applications to modern life, the physician has an added responsibility. More than ever he must be on his guard not only to diagnose the unforeseen pathologic patterns resulting from employment of new products and processes but also to protect the public if possible from their ill advised usage before untoward results occur.

The papers by Williams and Hempelmann published elsewhere in this issue of the *Journal* are examples of the type of diligence that must be observed in evaluating a newly commercialized device. From the careful data of Williams it is obvious that the use of such devices is not without danger. The variation of output and the protection provided among the apparatus tested varied widely. The amount of radiation received as direct

diation by the customer and as scattered radiation by the salesforce represents a real potential hazard. Certainly, no warning plate bearing the inscription demanded by the American Standards Association Code can assure any degree of safety. Attention is called to the fact that unattended machines have been observed in use by children and young adults to study not only the bones of the feet but also those of the hands.

For the average busy adult there is less danger than for a child. He requires fewer fittings and has less time to satisfy his curiosity. The growing child, with several changes in footwear a year, presents the problem, as pointed out by Hempelmann, for he is the one who will be exposed to unknown amounts of radiation throughout his life, particularly during the growing period, and the late changes to the skin and particularly to his epiphyseal development must be anticipated and prevented.

The average fitting for a pair of shoes will require a minimum of two exposures, one for the child to observe, and a second for the parent. A few of the latest machines have duplicate viewing facilities for child and adult. These exposures will increase directly with the number of pairs of shoes tried on, the number of relatives or friends present and the innate curiosity of the child. It will be the exceptional salesperson who will risk loss of a sale by strict observance of any so-called safety code. There is also nothing to prevent the customer from shopping around in other stores boasting these modern marvels of shoe fitting.

Supposing a child is exposed to an erythema dose — and Williams's data show that on several machines this is reached with a few exposures — the delay of a week or two before skin changes manifest themselves allows them to be unnoticed or at best to be attributed to irritating socks or hot feet. If this insult is repeated many times permanent skin damages not only result but also the danger of epiphyseal damage and resulting foot deformities is encountered.

Blood changes and damage to the sex glands are less likely to occur as a result of customer exposure, but they become a definite possibility among the salesforce of the store. Knowledge of the safe daily

amount of scattered radiation is far from complete. The maximum daily exposure thought to be safe has recently been scaled down from 0.1 r per day to 0.3 r per week as the result of studies made by the Advisory Committee on X-Rays and Radium.

The question raised by these papers is simply this: Are shoe-fitting fluoroscopes a necessity for the proper fitting of shoes or are they in effect sales promotional and of advertising value only — a form of window dressing? If the answer to the question is the latter they should be abandoned entirely. If the former answer is given, the strictest supervision is necessary, and unfortunately there is actually no safe method of making these restrictions work.

Fundamentally, the problem can be resolved only if machines, drugs and technics, particularly those giving off potentially dangerous radiation or having dangerous side reactions, are restricted in use to those whose training makes them competent to employ them.

THE CARE OF THE PATIENT

THE statement of the Committee on Diabetes of the Massachusetts Medical Society elsewhere in this issue of the *Journal* deserves careful attention, not only because it points out that valuable information concerning the discovery and treatment of diabetes will soon be available but also because it demonstrates an attitude that epitomizes the best in medical practice. Regardless of the present furore over the future status of medicine in the United States, the primary concern of the doctor is unchanged: the welfare of the patient comes first. The program outlined has no relation to propaganda for or against state medicine but the content of the message, which justifies the confidence of the patient in his physician, should be widely publicized.

In the midst of the present controversy, the proposed campaign is reassuring and edifying. The medical profession has not deviated from its ideal of service — the primary goal of ceaseless effort to find the best means of recognizing and curing disease. The tidings of what can be an immense forward step in the diagnosis and treatment of a

disease that is one of the major causes of death may well prove more effective than more emotional approaches to the public on the score of the future of medical practice organized medicine, not resting on its laurels or even emphasizing previous discoveries and achievements, is committed to progressive endeavor in all branches of the science of healing

Here, then, is information that may justifiably be incorporated in the educational program being conducted by the leaders of American medicine — to prove, to those who are ignorant of, or in doubt about, its aims, that to the medical profession the care of the patient comes first, if and how to regulate the service rendered are matters of secondary importance. The plan outlined, and others like it, may well affect the public's answer to the question of who is best fitted to control the practice of medicine

SEA-GOING ARMY

TO BE rocked in the cradle of the deep may yet become the pleasant experience suggested by the old song, according to the release earlier this year from the Department of the Army of the National Military Establishment. It may be that the sponsorship, by the Army Medical Department alone, of the now well known drug that acts as both a preventive and cure of seasickness implies a situation well in hand in the Navy, it may be that the boys in blue are simply willing to continue taking it on the chin and when the breezes blow to "generally go below."

Credit for the discovery of Dramamine, the salvation of those who go down to the sea in ships, belongs to Dr. Leslie N. Gay, of the Protein Clinic of Johns Hopkins University Hospital, and Dr. Paul Carlner, likewise a member of the Johns Hopkins staff. The United States Army Transport *Ballou*, loaded with more than 400 defenders of that which lies between the shining seas, provided the impressive clinical tests of the drug.

During an extremely rough passage in November, 1948, between New York and Bremerhaven, Germany, a total of 418 soldiers were treated with Dramamine. All were quartered in sub-level compartments. Complete relief from seasickness was obtained in 407 cases, with failure or only partial

relief in 11. No unpleasant symptoms resulted from the drug itself.

Various control tests were made. In the preventive study one group was given Dramamine, and another group sugar capsules on the same schedule. Of the men receiving Dramamine, none developed nausea, and only 2 of the 134 became dizzy. Of 127 men who received the sugar capsules, 35 became seasick within twelve hours. All were relieved when placed on the Dramamine.

Of those who had remained well on Dramamine, 41 developed seasickness after the drug was omitted, 40 of these recovered spectacularly when it was again administered. Other men on the ship became ill, 195 of them severely. Of this group 187 were completely relieved within an hour after taking the first dose of Dramamine.

It appears that this boon to humanity, a chemical cousin of Benadryl and Pyribenzamine, has robbed the ocean of at least one of its perils.

Perhaps it should have become a top military secret.

—Mrs. Elizabeth Dodd died at St. Stephens, New Brunswick, a few weeks since, at the age of 111 years. She was born on board a British ship of war in the Bay of Biscay — Ten days per annum is said to be the average sickness of human life.

Boston M. & S. J., August 29, 1849

MASSACHUSETTS MEDICAL SOCIETY

DIABETES DETECTION — A STATEMENT OF THE COMMITTEE ON DIABETES

THE existence of a large number of persons with diabetes undiagnosed and therefore untreated has been demonstrated by surveys not only in Massachusetts but elsewhere. There is need for the dissemination among physicians of information about the recent methods of treatment of diabetes by means of programs in district-society and hospital meetings. There is also a great opportunity and need to convey information to the public about the service the physician can give to patients with diabetes in all stages of the disease, but particularly

during the early stage. This affords an opportunity for carrying out the purpose of the National Education Campaign upon which the American Medical Association is now embarked. The purpose of this campaign is to demonstrate to the American people the services that physicians can render and are rendering to the American public in prevention of illness and the care of the sick.

The Committee on Diabetes of the Massachusetts Medical Society met in session on June 15, with representatives and presidents of fifteen of the district societies. They approved the program to be carried out in district societies aimed at disseminating information to the public by way of public meetings, the press and radio and at discovering patients with unrecognized diabetes so that they might come under medical treatment in doctors' offices and receive the benefits of modern treatment.

The Committee will have available an outlined plan for operation in any locality as well as printed material for distribution. A 16-mm, twenty-minute film in sound and color on diabetes for lay meetings has been prepared through the co-operation of the U. S. Public Health Service and the American Diabetes Association and will be available on loan through the office of the Massachusetts Department of Public Health. Strip films in color are also being prepared and will be available by loan to doctors for use in informing the public about diabetes and in treating patients.

New and simplified methods of self-testing, approved by the American Diabetes Association, will be available on sale at drug stores. These methods will make it possible for persons to make home tests of the urine following printed directions; these include advice to see the family physician for interpretation. Chemical materials for testing the urine will be provided by the manufacturers free of charge to any doctors' committee organized to carry out diabetes-detection programs, and approved by the district medical society, if application is made to the Massachusetts Committee on Diabetes, 8 The Fenway, Boston.

FIRST PRINCIPLES

To the Editor: Dr. Alexander's article in the July 14 issue of the *Journal* certainly fills us all with horror. The editorial comment upon it is most appropriate. However, I wonder if we are sufficiently horrified. Do we not realize that the same ideology that Dr. Alexander describes has already been insidiously introduced to us and accepted by many of us?

Let us read again the article by Dean Sperry in the *Journal* of December 23, 1948, and the editorial pertaining to it. In that article euthanasia is discussed but not condemned. In fact, the woman who did away with her husband was considered fortunate because she suffered no remorse.

Let us get back to first principles. Most of us give lip service to God as the creator of life. Why then do we presume to usurp His authority over life, its beginning, its functions and its end? We seem to set ourselves up as gods to decide who should be born and when, who should be sterilized, who should have a lobotomy, who should be put out of his misery. If we believe in God, why not leave such things to Him?

We seem to have lost the idea that the children and the aged, the insane and feeble-minded, the sick and the weak offer us a means of working out our own eternal salvation. I am afraid that we look at them either as nuisances or as sources of revenue.

If a thing is good, why not call it by its true name? It is only when we want to make an evil thing seem good that we invent a euphemistic name for it. Therefore we have therapeutic sterilization, therapeutic abortion, planned parenthood and euthanasia.

If called by their true names — mutilation for the purpose of sterilization, murder of the unborn, prostitution of marriage and murder in the first degree — they would be instantly rejected as horrible. Are we so easily deceived by euphemistic terminology that we do not see that we are in danger of becoming fiends rather than physicians?

MARGARET C. McMANIS, M.D.

Orange, Massachusetts

STAIGE D. BLACKFORD

To the Editor: Dr. Staige Davis Blackford of Charlottesville, Virginia, professor of the practice of medicine at the University of Virginia Department of Medicine and chief of gastroenterology at the University Hospital died on July 17. He was well known in Boston and New England because of medical service at the Massachusetts General Hospital and because of his associations with many New England men during World War II as medical-service chief of the Eighth Evacuation Hospital in North Africa and Italy.

He came from an old and distinguished Virginia family of clergymen, physicians and educators. Among his forebears in the earliest history of the old Dominion were the thoughtful, liberal and moderate Southerners who opposed slavery in a practical way by freeing their Negroes and paving for their repatriation in Africa. When the Civil War arose, this liberal tradition did not prevent the family members then living from serving the Confederacy in many capacities.

Staige Blackford's life exemplified the family traditions of liberalism and of loyalty. His service to his country in both world wars to his university and to his profession was as unrenouncing as it was selfless. His modesty, his forthright honesty, his always good-humored facility in exposing cant and pomposity, his disregard of personal ends brought public and academic recognition — some of us think, too little and too late. This irked his students and friends but not himself. His genius was friendship and sociability. He encouraged many colleagues young and old in their training and careers in their research and in their medical writing. His intimates knew him best as a skillful but always amiable disputant and conversationalist who loved the night-long ceaseless argument. A host of friends and patients are witnesses that while he was among us he

— loved no darkness

Sophisticated no truth

Nursed no delusion

Allowed no fears"

Boston

BOOK REVIEWS

Index-Catalogue of the Library of the Surgeon General's Office United States Army (Army Medical Library) Authors and subjects Fourth series, Vol X, M-Mez 4°, cloth, 994 pp Washington United States Government Printing Office, 1948 \$4 25

The *Index Catalogue* was created by an Act of Congress in 1879 and began publication in 1880 and is now in the middle of the fourth series. The material in each series is arranged alphabetically by author and subject in one alphabet. The first series consisting of sixteen volumes, published from 1880 to 1895, was edited by Dr John Shaw Billings, who brought the library to life after the Civil War and started it on its great career. The succeeding editions have been edited by Robert Fletcher, Fielding H Garrison and Claudius F Mayer, the present editor. In the first series Dr Billings endeavored to present all the literature contained in the collections of the library, either in books and pamphlets or in periodicals and serials. The second series, of twenty-one volumes, covered the period 1896-1916, and the third series, of ten volumes, 1918 to 1932. The fourth series, now in process of publication, consisting of ten volumes, A-Mc, 1936-1948, lists 7214 authors of books and pamphlets and 68,766 subject entries of material contained in books, pamphlets and periodicals. The subjects and their subdivisions total 6943. The last volume contains a check list of abbreviated titles of current publications received and indexed since 1919. Beginning at least with the third series, the indexing and publication of items became selective and did not represent the total number of titles of articles contained in the Library. The total number of volumes published to date is 57, covering a period of sixty-nine years. The total number of printed entries comprise 3,357,755, and the manuscript and printed catalogs of the Library total nearly 5,000,000 entries. The Army Medical Library is probably the largest and greatest medical library in the world. Its *Index Catalogue* provides for the world the greatest medical bibliography of all time. The great catalogs of the British Museum and the Bibliothèque nationale in Paris are devoted to the listing of all the manuscripts, books and pamphlets contained in these libraries. They do not list periodical and serial articles. In 1879 Dr Billings began the publication of the *Index Medicus*, a current monthly periodical of medical literature. This continued through various trials and tribulations until 1927, when it consolidated with the rival list of the American Medical Association to form the present *Quarterly Cumulative Index Medicus*. At the present time the continuance of the catalog and the future of the *QCIM* are being considered by the top authorities in Washington and Chicago, and the fate of the catalog hangs in the balance. Much of the great reputation of the Army Medical Library is based on the *Index Catalogue*, and with its continuance or discontinuance this reputation will rise or fall as the case may be. Its discontinuance would constitute an overwhelming calamity, and the medical world would suffer a great loss. It is hoped that the decision will be favorable to its continuance.

On the Contributions of Hugh Owen Thomas of Liverpool, Sir Robert Jones of Liverpool and London, John Ridlon, M.D., of New York and Chicago to Modern Orthopedic Surgery By H Winnett Orr, M.D. With a supplement on *Ridlon and His Share in Moulding Orthopedic Surgery*, by Arthur Steindler 8°, cloth, 253 pp Springfield, Illinois Charles C Thomas, 1949, \$4 50

In this volume Dr Orr discusses the works and accomplishments of three great orthopedic surgeons, two British and one American. Preceding the text proper are biographies of Thomas, Jones and Ridlon. The text is divided into eight chapters including a review of past and present methods in surgical practice (a review of past and present methods of surgical treatment, preface to several of Thomas's more important books), rest as a fundamental factor in the relief of pain and the arrest and cure of inflammation (introducing the famous Thomas splint), methods of obtaining rest in fractures and in articular disease, diagnosis and treatment of hip disease, disease of the knee joint, foot and ankle, the prevention and cure of disability and deformity in fractures, comments upon methods still in use in orthopedic practice, from the writings of H O Thomas, Sir Robert Jones and Dr John Ridlon, and the influence of Hugh Owen Thomas, Dr John

Ridlon and Sir Robert Jones upon each other and upon orthopedic surgery. A supplement by Dr Arthur Steindler discusses Dr Ridlon and orthopedic surgery. An annotated bibliography concludes the text. The volume is well published, but the lack of an index and a table of contents detracts from its reference value. The book should be in all medical libraries and available to surgeons and orthopedists.

Fighting Spotted Fever in the Rockies By Esther G Price. 8°, cloth, 269 pp., with 165 illustrations and frontispiece Helena, Montana Naegle Printing Company, 1948 \$4 00

In this popular book the author relates the story of the struggle to control and prevent Rocky Mountain spotted fever in Montana. The campaign began in 1901, and was continuously hampered by professional jealousy, hostility by large real-estate interests, politics and nonco-operation of the population. In 1913 the State passed an act establishing a board of entomology that eventually obtained the co-operation of the federal authorities, leading to concentrated research and the identification of the virus of the disease and the discovery of the Spencer-Parker preventive vaccine. From the first makeshift woodshed laboratory to the modern Rocky Mountain Laboratory at Hamilton, Montana, has been a long and dangerous journey, a number of the staff succumbing to the disease. The laboratory today produces annually vaccine enough for 140,000 persons in the United States, Canada and Brazil.

The disease was originally found in the western states from the Canadian border to Nebraska and extending to the eastern portions of the Pacific Coast states. It has now spread to the Middle Atlantic states. Today, there are only six states in which the disease has not been reported: Maine, Vermont, Rhode Island, Connecticut, Michigan and Kansas. Three ticks have been proved transmitting agents of the virus of the disease: the Rocky Mountain wood tick, the American dog tick, and the rabbit tick, the three together having a wide distribution throughout the United States, Canada and Alaska. Because of existing conditions, it will not be possible to eradicate the ticks completely, but the vaccine provides effective protection for exposed persons.

An appendix gives the state laws of Montana of 1913 and 1919 affecting tick-control work in the Bitter Root Valley. The text concludes with a bibliography, and there are indexes of names and subjects. The story of this dramatic campaign is told in an interesting narrative style. The book should be in all medical libraries and in all medical-history collections.

NOTICES

NEW ENGLAND HOSPITAL FOR WOMEN AND CHILDREN

The monthly clinical conference and meeting of the staff of the New England Hospital for Women and Children will be held in the classroom of the Nurses' Residence on Thursday, September 8 at 7 15 p m. Cases will be presented and discussed by Drs R Adelaide Draper, Constance Curtiss and Clara Waldinger. Dr Eliza A Melkon will be chairman.

NEW ENGLAND SOCIETY OF ANESTHESIOLOGISTS

A regular meeting of The New England Society of Anesthesiologists will be held in the auditorium of Building A Boston University School of Medicine, Boston, on Tuesday, September 13, at 8:00 p m.

A round-table discussion entitled "Respiratory Problems in Acute Poliomyelitis" will be conducted by Drs William Berenberg, Carl G Flake, David Grice and Stanley Sarnoff. Dr Robert M Smith will be moderator.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

Four sessions on research in medicine will be held in the Statler Hotel, New York, on December 28 and 29 as part of the 116th meeting of the American Association for the Advancement of Science.

These sessions are under the sponsorship of AAAS Section N, of which Dr Gordon K Moe, University of Michigan, is secretary.

THE PROFESSIONS IN THE SOCIETY OF TODAY*

ROSCOE POUND, LL D †

IN THE good old pioneer days in one of the younger western commonwealths a man conceived the idea that by putting a magnet in a box of ointment and leaving it there overnight he could produce a "magnetic ointment" with marvelous powers. He impressed a community with the value of his magnetic ointment and soon did a considerable business in making and selling it. On this he built up an extensive practice in the way of consultations with the ailing and prescribing different methods of using and applying the ointment according to the nature of the difficulty. Then came a statute requiring those who practiced medicine to take an examination and procure a license, and the old man, having neglected these formalities, was prosecuted and convicted of practicing medicine without a license. In passing sentence the trial judge spoke severely about amateur prescribing of quack remedies as a menace to the general health. At this the old man broke in protestingly. He said "Your Honor is calling me an amateur? Why, I have made more money in my business each of the last five years than all of any three licensed doctors in the county put together."

Undoubtedly the professional athlete, whose type is perhaps the professional baseball player, has confused popular ideas in this connection. The distinction between the professional and the amateur, of which we hear so much in the absorbing interest of sport, has done much to make a profession denote a money-making activity. In fifty years of teaching of law to students in the face of modes of thought engendered by sport, I have not found it easy to impart the conception of a group of men pursuing a common calling as a learned art and as a public service — nonetheless a public service because it may incidentally be a means of livelihood. From the Middle Ages the formative era of our social institutions, we had received this idea of a profession and medicine, the law, the ministry and teaching had grown up to its pattern. The conservatism of the universities and of professional schools on their model, and the inherited spirit of the apprentice training, which for a time succeeded

academic teaching of medicine and law in England and America, transmitted this idea to our time, and our books are full of it. But the idea was sorely tried under the reign of pioneer modes of thinking in nineteenth-century America. Moreover, many important callings have been claiming to rank with the older recognized professions as learned arts, taught in universities and pursued in a tradition of learning. Such are at least journalism, engineering, business administration, social work and public administration. In addition, almost all callings and activities have become organized and are pushing for every kind of recognition. Thus, we must inquire how far our older idea of a profession may be stretched to include socially or economically important callings of today and how that idea, stretched or not, is affected by the rise of the service state and its consequences in the society of the time.

Let me repeat what we mean by the term profession when we speak of the old recognized professions. We mean an organized calling in which men pursue a learned art and are united in the pursuit of it as a public service — as I have said, no less a public service because they may make a livelihood thereby. Here, from the professional standpoint there are three essential ideas — organization, learning and a spirit of public service. The gaining of a livelihood is not a professional consideration. Indeed, the professional spirit, the spirit of a public service, constantly curbs the urge of that instinct.

It is no disparagement of honorable trades and callings, which when properly carried on render real public service, to insist that an organized profession of physicians or of lawyers is not primarily analogous to a retail grocers' association and that there is a generic distinction between a medical society or an organized bar and a plumbers' or lumber dealers' association. It is unhappily true that there was in the last century in America a tendency to deprofessionalize the old professions, to reduce all callings to the level of individual business enterprise, and to think of medical societies or bar associations as like trade organizations. But the root purpose is different. The trade association exists for the purposes of the trade as a money-making

†University Professor Emeritus Harvard University formerly dean Harvard Law School.

activity The medical society exists primarily for the purposes of medicine, not of the doctor of medicine, and for the advancement of the healing art. The bar association exists primarily for the purposes of the law rather than of the lawyer and for advancement of the administration of justice according to law. Lord Darling spoke of certain legislation enacted at the instance of trade organizations as intended to relieve the members of those organizations from the humiliating position of being on an equality with the rest of the King's subjects. An organized profession, on the other hand, seeks no such legislation relieving it of duties incumbent upon it. It does not seek to advance the money-making feature of professional activity but seeks rather to make as effective as possible its primary character of a public service. What medical associations have done for advancement of medicine I need not recount to you. But I may remind you that bar associations have in the present generation lifted the standard of professional education, codified professional ethics, promoted uniformity of commercial law, and brought about simplification of legal procedure and removal of archaic technicalities. An engineer may patent his invention. A manufacturer may protect his trade secret or patent his discovered process. What a member of a profession invents or discovers is not his property. It is at the service of the public.

A tradition of duty of the physician to the patient, to the medical profession, and to the public, a tradition of the duty of the lawyer to the client, to the profession, to the court, and to the public, authoritatively declared in codes of professional ethics, taught by precept and example and made effective by the discipline of an organized profession, makes for effective service to the public such as could not be had from individual practitioners not bred to the tradition and motivated, as in a trade, primarily, if not solely, by quest of pecuniary gain. Nor can this professional tradition be replaced with benefit to the public by a political tradition of officeholders owing primary allegiance to political parties and depending for advancement on the favor of political leaders. Moreover, the professional organization and tradition are even more to the public interest in their effect on the learned arts than the professions follow as callings.

All advance in science, in arts, in learning, in short, all progress in civilization—in the raising of human powers to their highest possibilities—is the result of trial and error, that is, of experimentation. Every physician, every hospital, every lawyer, every law school, every teacher can and is impelled to experiment and invent, and as the professional spirit of public service leads to promulgation of the results of experiment and invention and putting the results freely at the service of others, they are not individual trade secrets and are not patented, they do not need to be argued to bureaus,

nor do those who would use them have to await official adoption of them. They are open to free use and make their way on their intrinsic merit.

Huge bureaus of graduates of medical schools and of law schools, brought up to seek public office and organized in the civil service as public employees, can be no effective substitute for the professions.

Unhappily, the public interest in having a body of practitioners of medicine and of law imbued with the spirit of a profession and by training and organization and discipline held to high standards of professional conduct was not so clear in pioneer America as it is today. The idea of a profession seemed repugnant to rising American democracy. The feeling was strong that all callings should be on the same footing, namely, the footing of a business—of a money-making calling. To dignify any calling by holding it a profession, and to prescribe high qualifications for and limit access to it, seemed undemocratic and un-American. Moreover, pioneer America distrusted specialists. Faith in versatility was pre-eminently an article in the pioneer's creed. In consequence, there was a general rejection of the idea of a learned, responsible, self-governing profession. You know what the situation was in medicine when in 1910 the American Medical Association with the help of the Carnegie Foundation took medical education in hand. Let me tell the story of the law to make the point further. Some states threw the practice of law open to nonlawyers, with bad effects on legal procedure some of which are still manifest, and, indeed the legal osteopath and legal chiropractor and legal faith healer have been as favored by American legislators as have their medical counterparts. Some states that retained a requirement of admission to the bar provided that anyone was to be admitted with no other qualification than lack of a conspicuously bad character. All the states, by legislation or by increasingly lax administration of their requirements and lack of public or professional interest in the matter, made entrance upon practice easy with a minimum of qualification. As population increased, and large numbers of lawyers were admitted in great urban centers, discipline became lax, and many forensic abuses, such as offensive conduct toward witnesses and abuses in the fomenting of litigation, grew up. As the practice of law was regarded as only a business, organizations grew up in large cities in which lawyers, physicians, runners and even professional witnesses came to be engaged in preying alike upon the victims of accidents and those responsible for accidents. Experience taught us the value of the professional tradition and of the distinction between a profession and a trade. Reprofessionalization has gone forward steadily for two generations.

But reprofessionalization had hardly been achieved when the idea of a profession began to be subjected to new pressure.

From the beginning, American political thought had been dominated by fear of governmental oppression of the individual. Those who colonized America had been brought up in an atmosphere of resistance to the centralized personal government of the Tudors and Stuarts, and experience of arbitrary government of the colonies from Westminster had strengthened their feeling. Coincident with the movement for reprofessionalizing the old professional callings, however, there has been a change in the American attitude toward government. In a recent book Professor Corwin has written of the decadence of the fear of governmental oppression. Throughout the world the present century has seen a steady rise of the idea of the service state — the state that performs all manner of services for the people instead of leaving them as free as possible to serve themselves or to procure services for themselves according to their individual ideas of what they need or what they wish. I am not here to speak against the service state. In an age of big-ness other interests than the social interest in the general security press for recognition, and the state that merely keeps the peace and maintains order does not satisfy. But with the multiplication of services rendered by the state comes a multiplication of officials, and ideas of official omniscience and majority infallibility come also. When every form of public service becomes at least potentially a state function, the difference between a public service performed by a profession and a public function performed by a bureau becomes crucial. The one becomes a matter of free enterprise, and the other one of politically regimented activity.

Accordingly, I seem to see four sources of menace to the professional ideal in the society of today. One, the exigencies of the individual economic existence, has always been with us. It is simply magnified in the crowded world of the time. A second is the multiplication of detail in every branch of learning, and notably in the learned arts pursued by the members of a profession. Nowadays these details are multiplied beyond what the individual practitioner can hope to master completely. There is consequent need of co-operation of practitioners leading to partnerships of increasing size and conceivably even to corporations in which individual responsibility may become merged. Thirdly, when this stage has been reached it is difficult to resist the pressure of business methods, which easily become the methods of competitive acquisitive activity. Fourthly, all this goes along with and is given impetus by the advent of the service state and consequent growing tendency to rely on official rather than on individual private initiative and to commit all things to bureaus of politically organized society.

Let me illustrate from the legal profession what you can no doubt duplicate from your profession,

the difference between the last century and the present.

In November, 1890, two farmers in the county where I had been admitted to the bar, being advised each by his lawyer that a doubtful point of law was decisive of their dispute and that if litigated it would have to be taken to the Supreme Court for final determination, agreed to submit the question of law to the opinion of a well known lawyer in the capital of the state from which they both had come. Accordingly an agreed statement of the facts, which were not controverted, was drawn up, and I was sent with it by agreement of the parties to obtain the desired opinion. The lawyer whose opinion I was to get was one of the leaders of the bar in not the least of the states of the Middle West. His office around the corner from a main street of the capital city, was a one-story brick building from which there hung over the sidewalk a small, weather beaten sign, "Notary Public." Going in at the front door I found a room furnished with the wooden cuspidors of the period and old-fashioned chairs such as we used to see on the sidewalks in front of country hotels, and with the walls lined with bookcases extending to the ceiling and full of books. There was a long table in the middle of the room with law books and a Webster's Dictionary on it. In one corner there was a combination desk and bookcase at which sat one whom I took to be a clerk. In another corner one whom I took to be a student "reading law," as the phrase then was, had a book open before him. Having stated my business to the clerk, I was soon admitted to the inner office, which was furnished much as the outer room. The lawyer presently looked up from some papers he was reading and said he was at my service. I handed him the agreed statement of facts and explained that his written opinion on their legal effect was desired. He asked if there was any statute on the subject in the state from which I had come to him. I told him there was not, nor had the question of law been passed on by the Supreme Court of that state. It was a question of common law, and hence his written opinion was desired. He looked over the statement of facts once more, tapped the table with his fist a few times, pulled a few sheets of legal cap paper out of a drawer and then and there wrote out by hand a three-page opinion in ink, which he handed me. I had come prepared to pay a fairly large fee, but he had endorsed a relatively small one on the opinion and when I paid it he receipted it in the same place. Such was the office of a leader of the bar in the consulship of Plancus.

A few years ago a lawyer from a rural county-seat in Maine had occasion to call upon one of the leaders of the bar in Boston. Going up in the elevator in a large office building he found the leader's firm occupying two floors. There was a great room like a court, where he went in. Around it were

office rooms on all sides and above were more rooms all around on a balcony. In the middle of the court-like space was a desk in charge of a "receptionist." Typewriters were clicking all about, many people were seated about the room, and many were hurrying in and out of the office rooms. The astonished country lawyer went up to the receptionist and said "I want a room with bath."

It is not easy to maintain the professional ideal in such an atmosphere of a great law factory. What keeps it alive is the professional tradition. But one may question whether it could be kept alive if for the metropolitan law office we were to substitute a huge government bureau. Certainly the ideal is strained in the legal departments of some great public utilities with their staffs of lawyers, law clerks, investigators and experts. Some great industrial enterprises have such legal departments also. Whether medical departments approaching this have been growing up I do not know. At any rate, the tendency of our economic development, as it affects the legal profession, is to bring about something very like a class of employees of corporations called law clerks who may yet be seen forming a law clerk's union affiliated with the CIO, and exerting themselves not to advance the administration of justice but to advance the compensation of law clerks. An incidental bad effect of this course of development of the metropolitan lawyer is that the bar often comes to be divided into two classes, habitual plaintiff's lawyers and habitual defendant's lawyers, each with its staff of lawyers, law clerks, experts and, one suspects, witnesses. Already we have great administrative bureaus of the national government and of state governments, each often with its legal and medical and technical staff.

Economic expansion, the growth of industry, the multiplying of metropolitan cities and the new relations calling for adjustment and new problems of ordering the conduct of enterprises and the relations involved in them have called for the type of office I have described. It is a natural and inevitable response to them. But even more the professional ideal is menaced by the development of great government bureaus and a movement to take over the arts practiced by the professions and make of them functions of the government to be exercised by its bureaus in a superservice state that may become a service super-state. For the idea of a profession is incompatible with performance of its functions or the exercise of its art, by or under the immediate supervision of a government bureau. A profession postulates individuals free to pursue a learned art so as to make for the highest development of human powers. The individual servant of a government exercising under its supervision a calling managed by a government bureau can be no substitute for the scientist, the philosopher, the teacher, each freely exploring his chosen field

of learning and exercising his inventive faculties and trained imagination in his own way, not as a subordinate in a bureaucratic hierarchy, not as a hired seeker for what he is told to find by his superiors, but as a free seeker for the truth for its own sake, impelled by the spirit of public service inculcated in his profession.

If all callings are but money-making activities and making of a livelihood is their primary concern, it follows, in an economic order in which the great majority of the community are on the payroll either of the government or of some corporation, public, public service, charitable, or private, that most of us are in a sense employees and so liable to be caught up in a regime of employees' organizations, collective bargaining over wages and strikes. Organization of physicians for advancement of medicine, organization of lawyers for advancement of the administration of justice and organization of teachers for the advancement of teaching must give way to organization of employees of every grade and kind of employer for the advancement of wages and dictation of the conditions of employment. Already the two major labor organizations are carrying on a campaign to unionize the "white-collar workers" in industry and business. This may well presently take in the younger members of the bar in the legal departments of large companies. Already the American Federation of Labor has organized municipal employees, and in Los Angeles the probation officers, whom we had been thinking of as members of a rising profession of social workers, are members of the Probation Officers' Union, a branch of the Municipal Employees' Union, affiliated with the national organization. The National Labor Relations Board held and was upheld by the Supreme Court of the United States in holding that plant guards during the war, enlisted at first as soldiers and later made part of city police forces, could be organized in unions by the Congress of Industrial Organizations. Are the young lawyers in the office of a city attorney, along with the clerks and stenographers, the municipal probation officers, the clerks, secretaries and typists in the various city departments, the firemen and the policemen, to be in a union of municipal employees and from time to time to strike for increased pay as collective bargain contracts expire or when one of their number is removed or discharged? Next, county employees may be organized as such so that the clerical force in the courthouse may go on a strike and tie up the administration of justice. Are the assistant district attorneys to be unionized also? May we not see unions of state employees and find the secretaries of the judges of the Supreme Court striking? Already there are unions of federal employees, and these may come to include the young men, members of the bar, who are secretaries to the justices of the highest court in the land. Every department and major ad-

ministrative agency of the federal Government has many lawyers on its roster. Unions of federal employees will seek to include them. Moreover, the law reports show that the courts have come to be much troubled to determine whether and when physicians in a hospital are independent contractors and when they are employees of a charitable corporation.

Teachers in the public schools have been unionized in more places than one, and members of university faculties are now active in a teachers' union in some of our old historic institutions. Are we to see closed shops of higher learning with union faculties collectively bargained with, check off for union dues and all the concomitants of organized pursuit of higher wages in what had been thought a learned profession?

Thus as things are coming to be in an era of bigness, large-scale organization of all activities and strenuous acquisitive competitive self assertion the professional idea must contend with the rise to power of organizers of an expanding class of employees. Thus more and more as things are, as individuals in the professions have come to be regularly retained or nowadays regularly employed by great corporations or appointed to substantially permanent positions under the federal Government or state and municipal governments and administrative agencies a constantly larger number of practitioners in their capacity of employees are enlisted in organizations with the trade spirit of emphasis on wages rather than the professional idea of pursuit of a calling in the spirit of public service. Unless we are vigilant it may well be that this prevailing of the trade idea will make straight the path toward absorption of the professions in the service state. The course of that path is not hard to plot. We can see three possible stages: unionizing of all callings that may be taken to involve employment, at least so far as some in the calling are not capable of classification as employers, assumption of control of professional education by government subsidies and thus subordination of the professions to bureaucratic management, attempts to bring cheap and equal professional assistance to everyone's back door by government taking over of the callings pursuing learned arts. Such a consummation may be pictured as a carrying of the idea of the service state to its furthest logical development. The service state began by performing a few major services. In time it has undertaken more and more. Now it seems jealous of public service performed by anyone else. The advocates of the omniscient state will say that in primitive or pioneer societies certain public services are rendered by anyone who seeks to try his hand on the basis of such qualifications as he deems sufficient. Later as society advances such services are rendered by well qualified practitioners organized in professions,

the qualifications, as these professions develop, being prescribed and ascertained by governmental authority. Ultimately, it will be said, as political organization of society reaches maturity, all public services of every sort are to be exclusive governmental functions to be exercised by government bureaus.

Very likely, not all those who are teaching or preaching the doctrine of the super-service state will at the moment admit this conclusion. But I submit that before we go far with them on the path in which they are marching we should pause to see whither it leads. It should be remembered that the rise of the totalitarian state was coincident with the general reception of the idea of the service state and that both have Marxian socialism in their pedigree. Each in its way postulates an omniscient administration by supermen. If experience may be vouched that means in the end supermen under the direction of an *ex-officio* superman.

But leaving aside the question of the effect upon our American constitutional democratic polity of carrying the idea of the service state to its furthest development, let us look more in detail at the effect of that idea, as it is being urged, upon the professions.

Practice of medicine and practice of law the ministry and teaching are each of them essentially an individual learned art. Each is an art in which the individual approach of a skilled practitioner to the task immediately in hand is of first importance. He can not be made to a model so that every one can have the benefit of a professional man exactly as good for every purpose as everyone else has. The required combination of training, native skill and experience makes each practitioner in some measure and in varying degrees unique. No bureau and no super-administrator at a center of government, especially in a country of continental extent like our own, can co-ordinate all medical treatment, all medical research, all advocacy, all juristic inventiveness, all spiritual help or preaching, or all teaching, so that every locality and every citizen shall have the same advantages as every other. The professional ideal however, promotes effective individual treatment, individual counsel and forensic exertion, individual ministry and individual teaching, to the best of the powers of the individual practitioner, minister or teacher. Such things do not lend themselves to paper reports and mechanically produced uniformity and equality. The attempt to produce them may reduce the performance of the highest skills to a lower level of performance without raising the quality of lower skills or lesser experience. Uniform governmental management would sacrifice the reality of the public service sought to the exigencies of statistical and bureau-chart methods.

Government-managed religion was given up centuries ago. But centralized government manage-

office rooms on all sides and above were more rooms all around on a balcony. In the middle of the court-like space was a desk in charge of a "receptionist." Typewriters were clicking all about, many people were seated about the room, and many were hurrying in and out of the office rooms. The astonished country lawyer went up to the receptionist and said "I want a room with bath."

It is not easy to maintain the professional ideal in such an atmosphere of a great law factory. What keeps it alive is the professional tradition. But one may question whether it could be kept alive if for the metropolitan law office we were to substitute a huge government bureau. Certainly the ideal is strained in the legal departments of some great public utilities with their staffs of lawyers, law clerks, investigators and experts. Some great industrial enterprises have such legal departments also. Whether medical departments approaching this have been growing up I do not know. At any rate, the tendency of our economic development, as it affects the legal profession, is to bring about something very like a class of employees of corporations called law clerks who may yet be seen forming a law clerk's union affiliated with the CIO, and exerting themselves not to advance the administration of justice but to advance the compensation of law clerks. An incidental bad effect of this course of development of the metropolitan lawyer is that the bar often comes to be divided into two classes, habitual plaintiff's lawyers and habitual defendant's lawyers, each with its staff of lawyers, law clerks, experts and, one suspects, witnesses. Already we have great administrative bureaus of the national government and of state governments, each often with its legal and medical and technical staff.

Economic expansion, the growth of industry, the multiplying of metropolitan cities and the new relations calling for adjustment and new problems of ordering the conduct of enterprises and the relations involved in them have called for the type of office I have described. It is a natural and inevitable response to them. But even more the professional ideal is menaced by the development of great government bureaus and a movement to take over the arts practiced by the professions and make of them functions of the government to be exercised by its bureaus in a superservice state that may become a service super-state. For the idea of a profession is incompatible with performance of its functions or the exercise of its art, by or under the immediate supervision of a government bureau. A profession postulates individuals free to pursue a learned art so as to make for the highest development of human powers. The individual servant of a government exercising under its supervision a calling managed by a government bureau can be no substitute for the scientist, the philosopher, the teacher, each freely exploring his chosen field

of learning and exercising his inventive faculties and trained imagination in his own way, not as a subordinate in a bureaucratic hierarchy, not as a hired seeker for what he is told to find by his superiors, but as a free seeker for the truth for its own sake, impelled by the spirit of public service inculcated in his profession.

If all callings are but money-making activities and making of a livelihood is their primary concern, it follows, in an economic order in which the great majority of the community are on the payroll either of the government or of some corporation, public, public service, charitable, or private, that most of us are in a sense employees and so liable to be caught up in a regime of employees' organizations, collective bargaining over wages and strikes. Organization of physicians for advancement of medicine, organization of lawyers for advancement of the administration of justice and organization of teachers for the advancement of teaching must give way to organization of employees of every grade and kind of employer for the advancement of wages and dictation of the conditions of employment. Already the two major labor organizations are carrying on a campaign to unionize the "white-collar workers" in industry and business. This may well presently take in the younger members of the bar in the legal departments of large companies. Already the American Federation of Labor has organized municipal employees, and in Los Angeles the probation officers, whom we had been thinking of as members of a rising profession of social workers, are members of the Probation Officers' Union, a branch of the Municipal Employees' Union, affiliated with the national organization. The National Labor Relations Board held and was upheld by the Supreme Court of the United States in holding that plant guards during the war, enlisted at first as soldiers and later made part of city police forces, could be organized in unions by the Congress of Industrial Organizations. Are the young lawyers in the office of a city attorney, along with the clerks and stenographers, the municipal probation officers, the clerks, secretaries and typists in the various city departments, the firemen and the policemen, to be in a union of municipal employees and from time to time to strike for increased pay as collective bargain contracts expire or when one of their number is removed or discharged? Next, county employees may be organized as such so that the clerical force in the courthouse may go on a strike and tie up the administration of justice. Are the assistant district attorneys to be unionized also? May we not see unions of state employees and find the secretaries of the judges of the Supreme Court striking? Already there are unions of federal employees, and these may come to include the young men, members of the bar, who are secretaries to the justices of the highest court in the land. Every department and major ad-

surgeons' strikes, or lawyers' strikes, or ministers' strikes, which are foreshadowed by the impairment of the professional idea and the dominance of the idea of all callings as mere means of gaining a livelihood. Even less does the rise of the service state require to lead to setting up of the totalitarian state. Here, too, a balance is required, however easy it may be to go, as man is so likely to go, from one extreme to the other and then back again.

After all the individual man is the moral, social and legal unit. Certain of his activities may be organized in groups and associations and political societies. But his personality is not merged in any of them. Recognition of the moral worth of the individual human being is the great achievement of the political and juristic philosophy of the eighteenth and nineteenth centuries. Appreciation of the social interest in the individual life is the significant achievement of the social philosophy of the present generation. It is not likely that any

political or economic order that may supervene in such time as we can foresee will succeed in putting down the individual self-assertion that has been a motive force of progress. But the attempt to put it down with a sole eye to regimented co-operation may do a great deal of harm.

There has always been a human tendency to worship rulers. Today, majority dictation is often revered as the monarch's arbitrary dictation was in the seventeenth century. Lord Acton tells us that all power corrupts, absolute power corrupts absolutely. Majority-dictated science, majority-dictated philosophy and majority-dictated teaching take us back to the absolute rulers whom we set up majority rule to overthrow. The service state is a political step forward. But we must not let it turn back upon itself and lead us to absolutism. There is no surer route to absolutism than an unchecked omniscient bureaucracy.

PSEUDOMYXOMA PERITONEI ASSOCIATED WITH CHOLESTEROSIS*

C. G. TEDESCHI, M.D.,† E. A. GASTON, M.D.,‡ AND ETHAN A. BROWN, M.D.§

BOSTON AND FRAMINGHAM, MASSACHUSETTS

WERTH,¹ in 1884, first called attention to the unusual finding of a gelatinous exudate, partly free and partly encysted, in the peritoneal cavity of a woman bearing a "pseudomucinous cyst" of the ovary. He named the process "pseudomyxoma peritonei" and traced its origin to the rupture of the ovarian cyst and subsequent implant of the cystic contents on the peritoneal membranes. In 1901 Fraenkel² found a similar condition in a man with a ruptured mucocele of the appendix. Because of the gross similarity of patterns he considered it appropriate to retain the denomination previously proposed by Werth.¹

Since then quite an extensive literature has accumulated concerning this comparatively infrequent process. It is now well established that "pseudomyxoma peritonei" is not a disease in itself but an unpredictable complication occurring in the course of a variety of intra-abdominal conditions, including ovarian cyst-adenoma, mucocele of the appendix, omphalomesenteric cyst, intestinal diverticulum and retroperitoneal cystadenoma. Most unusual in this respect is the case described by McCrac and Coplin,³ in which the condition developed as a sequel to a gall-bladder carcinoma.

For a clear understanding of the process two main problems must be considered:

The first concerns the retention of the mucinoid material in the secreting viscus.

Obstruction of the appendiceal lumen and inability of the appendix to empty itself have been considered responsible for the mucocele of the appendix.² As the glands in the appendix continue to secrete, the organ gradually becomes distended with mucus. The resulting increase in internal pressure leads to thinning and eventually to rupture of the walls of the appendix, with resulting extrusion of the mucous content into the peritoneal cavity. The experimental work of Grodinsky and Rubnitz⁴ and of Rubnitz and Hermann⁵ has contributed considerable information explaining this sequence of events. This applies also to the "pseudomyxoma peritonei" resulting from the obstruction and rupture of an intestinal diverticulum.⁶

As for the "pseudomyxoma peritonei" of neoplastic origin the accumulation of secretion within the tumor mass is self-explained by the intrinsic nature of the process.

More difficult to understand is the second problem, the one concerning the continuation of secretion of the matter, whatsoever its source, escaped within the abdominal cavity. Many theories have been advanced to explain this point, but the one still most favorably accepted is Fraenkel's² original view of a seeding of the peritoneal membranes with secreting cells, subsequent cellular proliferation and mucous secretion.

ment of medicine, advocacy and teaching are becoming live issues, and, as you know, the threat to medicine as a profession is especially acute. The same objection to government-managed religious worship — namely, that it eliminated the spirit that gives life — applies, as has been said, in the other professions, no less than in the ministry. Their whole purpose is defeated if practice of them falls into a mechanical routine. Moreover, in the democratic polity of today, government-managed medicine, government-managed advocacy or government-managed teaching means putting these fundamental social needs into politics, and not the least bad effect of putting them in politics is that it becomes no longer possible for the people to get non-political expert advice, such as at times they need sorely. This is true not only of government-managed professions but also quite as much of government-subsidized institutions.

Under a system by which local funds for research or for teaching are derived from the national capital even the small part allocated to a locality imposes a kind of censorship on the local authorities. In their eagerness to share in the governmental distribution local officials are loth to make statements or espouse ideas out of conformity with the political or economic doctrines or aims of the central administration or in conflict with the scientific doctrines that its bureaus advocate. Government propaganda goes on upon a large and increasing scale, and dissent is silenced. The effect of this upon a learned art pursued in the spirit of a public service cannot fail to be destructive. How can scientists disagree with the government-promoted doctrines, how can advocates stand up against arbitrary bureaucratic administrative action, how can teachers teach the truth against officially approved doctrines when disagreement means failure to get government grants for research or government subsidies for the institution in which one is employed, or government appointments or assignments to salaried positions?

Aristotle thought that if the individual was not allowed to choose his physician but must go to the one assigned to him by the magistrate under a law, it would be necessary to have the law fix the definitely prescribed prescription for every specific ill. This would carry mechanical therapy to the extreme. But he did not join to it bureau-dictated research and investigation.

Understand me. I am not preaching against the service state in itself. The society of today demands services beyond those which the state that only maintained order and repaired injuries could perform. Administrative agencies of promoting the general welfare have become a necessity and are with us to stay. It would be futile to quarrel with the idea of a service state kept in balance with the idea of individual spontaneous initiative characteristic of the American. What one must resist is

not state performance of many public services but the idea that all services must and can only be performed by the government. The need is to maintain a balance between individual initiative and regimented co-operation. What I deprecate is the carrying of the idea of regimented co-operation to the extreme — the exaltation of politically organized society to the position of an absolute ruler. It is not easy for mankind to keep in mind at the same time two ideas that logically negate each other if each is carried to the extreme of its logical possibilities. But this must often be done. To take but one example from our criminal law, we have to keep in mind continually both the idea of justice, the ideal relation among men, and the idea of security. The idea of security calls for a maximum efficiency of criminal investigation and detection. Carried to its farthest it could, at least in extreme cases, be made to justify the third degree — the extortion of confessions by brutal treatment of suspected offenders. On the other hand, such methods are repugnant to the idea of justice and to another idea we must not lose sight of in the law — namely, the ideal of morals, the idea of ideal development of individual character, to which the third degree and like methods of criminal investigation are no less repugnant. When we think only in terms of the general security we make no objection to extorting confessions, to holding incommunicado, to searches of homes and seizures of papers and to wire tapping. When we think only in terms of justice or of morals we go to the extreme of hampering criminal investigation by rigid provisions in bills of rights such as were at times, at least in their application, carried beyond reasonable limits in nineteenth-century America. We have not yet succeeded in adjusting satisfactorily the conflicting requirements of these ideas.

I have often compared this problem of politics and law to the task of the juggler in the circus who keeps a succession of glass balls in the air at once, back and forth from his hand, never losing sight of any nor giving any one too exclusive attention. We have such a problem in the rise of the service state. Its requirements and its logical limits are not the whole of the science of politics any more than the requirements and logical limits of the general security are the whole of the science of criminology.

Casting off of the past is not the whole of progress. Institutional waste, the needless destruction of the old in introducing the new, has always to be guarded against. It would be nothing less than institutional waste to throw away the idea of a profession in order to develop services to be performed by government that politically organized society in the last century made no attempt to provide. A reasonable development of the service state does not require such things as the teachers' strikes we are beginning to see, much less the physicians' or

surgeons' strikes, or lawyers' strikes, or ministers' strikes, which are foreshadowed by the impairment of the professional idea and the dominance of the idea of all callings as mere means of gaining a livelihood. Even less does the rise of the service state require to lead to setting up of the totalitarian state. Here, too, a balance is required, however easy it may be to go, as man is so likely to go, from one extreme to the other and then back again.

After all the individual man is the moral, social and legal unit. Certain of his activities may be organized in groups and associations and political societies. But his personality is not merged in any of them. Recognition of the moral worth of the individual human being is the great achievement of the political and juristic philosophy of the eighteenth and nineteenth centuries. Appreciation of the social interest in the individual life is the significant achievement of the social philosophy of the present generation. It is not likely that any

political or economic order that may supervene in such time as we can foresee will succeed in putting down the individual self-assertion that has been a motive force of progress. But the attempt to put it down with a sole eye to regimented co-operation may do a great deal of harm.

There has always been a human tendency to worship rulers. Today, majority dictation is often revered as the monarch's arbitrary dictation was in the seventeenth century. Lord Acton tells us that all power corrupts, absolute power corrupts absolutely. Majority-dictated science, majority-dictated philosophy and majority-dictated teaching take us back to the absolute rulers whom we set up majority rule to overthrow. The service state is a political step forward. But we must not let it turn back upon itself and lead us to absolutism. There is no surer route to absolutism than an unchecked omniscient bureaucracy.

PSEUDOMYXOMA PERITONEI ASSOCIATED WITH CHOLESTEROSIS*

C. G. TEDESCHI, M.D.,† E. A. GASTON, M.D.,‡ AND ETHAN A. BROWN, M.D.§

BOSTON AND FRAMINGHAM, MASSACHUSETTS

WERTH,¹ in 1884, first called attention to the unusual finding of a gelatinous exudate, partly free and partly encysted, in the peritoneal cavity of a woman bearing a "pseudomucinous cyst" of the ovary. He named the process "pseudomyxoma peritonei" and traced its origin to the rupture of the ovarian cyst and subsequent implant of the cystic contents on the peritoneal membranes. In 1901 Fraenkel² found a similar condition in a man with a ruptured mucocele of the appendix. Because of the gross similarity of patterns he considered it appropriate to retain the denomination previously proposed by Werth.¹

Since then quite an extensive literature has accumulated concerning this comparatively infrequent process. It is now well established that "pseudomyxoma peritonei" is not a disease in itself but an unpredictable complication occurring in the course of a variety of intra-abdominal conditions, including ovarian cyst-adenoma, mucocele of the appendix, omphalomesenteric cyst, intestinal diverticulum and retroperitoneal cystadenoma. Most unusual in this respect is the case described by McCrae and Coplin,³ in which the condition developed as a sequel to a gall-bladder carcinoma.

For a clear understanding of the process two main problems must be considered:

*From the Department of Pathology and Surgery of the Framingham Union Hospital and Boston University School of Medicine.

†Instructor in pathology, Boston University School of Medicine; director of laboratories, Framingham Union Hospital.

‡Assistant professor of surgery, Boston University School of Medicine; surgeon-in-chief, Framingham Union Hospital.

§Physician-in-chief, Allergy Section, New England Medical Center; lecturer in medicine, Tufts College Medical School.

The first concerns the retention of the mucinoid material in the secreting viscus.

Obstruction of the appendiceal lumen and inability of the appendix to empty itself have been considered responsible for the mucocele of the appendix.² As the glands in the appendix continue to secrete, the organ gradually becomes distended with mucus. The resulting increase in internal pressure leads to thinning and eventually to rupture of the walls of the appendix, with resulting extrusion of the mucous content into the peritoneal cavity. The experimental work of Grodinsky and Rubnitz⁴ and of Rubnitz and Hermann⁵ has contributed considerable information explaining this sequence of events. This applies also to the "pseudomyxoma peritonei" resulting from the obstruction and rupture of an intestinal diverticulum.⁶

As for the "pseudomyxoma peritonei" of neoplastic origin the accumulation of secretion within the tumor mass is self-explained by the intrinsic nature of the process.

More difficult to understand is the second problem, the one concerning the continuation of secretion of the matter whatsoever its source escaped within the abdominal cavity. Many theories have been advanced to explain this point but the one still most favorably accepted is Fraenkel's² original view of a seeding of the peritoneal membranes with secreting cells; subsequent cellular proliferation and mucous secretion.

ment of medicine, advocacy and teaching are becoming live issues, and, as you know, the threat to medicine as a profession is especially acute. The same objection to government-managed religious worship — namely, that it eliminated the spirit that gives life — applies, as has been said, in the other professions, no less than in the ministry. Their whole purpose is defeated if practice of them falls into a mechanical routine. Moreover, in the democratic polity of today, government-managed medicine, government-managed advocacy or government-managed teaching means putting these fundamental social needs into politics, and not the least bad effect of putting them in politics is that it becomes no longer possible for the people to get non-political expert advice, such as at times they need sorely. This is true not only of government-managed professions but also quite as much of government-subsidized institutions.

Under a system by which local funds for research or for teaching are derived from the national capital even the small part allocated to a locality imposes a kind of censorship on the local authorities. In their eagerness to share in the governmental distribution local officials are loth to make statements or espouse ideas out of conformity with the political or economic doctrines or aims of the central administration or in conflict with the scientific doctrines that its bureaus advocate. Government propaganda goes on upon a large and increasing scale, and dissent is silenced. The effect of this upon a learned art pursued in the spirit of a public service cannot fail to be destructive. How can scientists disagree with the government-promoted doctrines, how can advocates stand up against arbitrary bureaucratic administrative action, how can teachers teach the truth against officially approved doctrines when disagreement means failure to get government grants for research or government subsidies for the institution in which one is employed, or government appointments or assignments to salaried positions?

Aristotle thought that if the individual was not allowed to choose his physician but must go to the one assigned to him by the magistrate under a law, it would be necessary to have the law fix the definitely prescribed prescription for every specific ill. This would carry mechanical therapy to the extreme. But he did not join to it bureau-dictated research and investigation.

Understand me. I am not preaching against the service state in itself. The society of today demands services beyond those which the state that only maintained order and repaired injuries could perform. Administrative agencies of promoting the general welfare have become a necessity and are with us to stay. It would be futile to quarrel with the idea of a service state kept in balance with the idea of individual spontaneous initiative characteristic of the American. What one must resist is

not state performance of many public services but the idea that all services must and can only be performed by the government. The need is to maintain a balance between individual initiative and regimented co-operation. What I deprecate is the carrying of the idea of regimented co-operation to the extreme — the exaltation of politically organized society to the position of an absolute ruler. It is not easy for mankind to keep in mind at the same time two ideas that logically negate each other if each is carried to the extreme of its logical possibilities. But this must often be done. To take but one example from our criminal law, we have to keep in mind continually both the idea of justice, the ideal relation among men, and the idea of security. The idea of security calls for a maximum efficiency of criminal investigation and detection. Carried to its farthest it could, at least in extreme cases, be made to justify the third degree — the extortion of confessions by brutal treatment of suspected offenders. On the other hand, such methods are repugnant to the idea of justice and to another idea we must not lose sight of in the law — namely, the ideal of morals, the idea of ideal development of individual character, to which the third degree and like methods of criminal investigation are no less repugnant. When we think only in terms of the general security we make no objection to extorting confessions, to holding incommunicado, to searches of homes and seizures of papers and to wire tapping. When we think only in terms of justice or of morals we go to the extreme of hampering criminal investigation by rigid provisions in bills of rights such as were at times, at least in their application, carried beyond reasonable limits in nineteenth-century America. We have not yet succeeded in adjusting satisfactorily the conflicting requirements of these ideas.

I have often compared this problem of politics and law to the task of the juggler in the circus who keeps a succession of glass balls in the air at once, back and forth from his hand, never losing sight of any nor giving any one too exclusive attention. We have such a problem in the rise of the service state. Its requirements and its logical limits are not the whole of the science of politics any more than the requirements and logical limits of the general security are the whole of the science of criminology.

Casting off of the past is not the whole of progress. Institutional waste, the needless destruction of the old in introducing the new, has always to be guarded against. It would be nothing less than institutional waste to throw away the idea of a profession in order to develop services to be performed by government that politically organized society in the last century made no attempt to provide. A reasonable development of the service state does not require such things as the teachers' strikes we are beginning to see, much less the physicians' or

With the preoperative diagnosis of "pseudomyxoma peritonei" an exploratory laparotomy was performed. From 6 to 7 liters of gelatinous, yellowish-gray, translucent material was found in the abdominal cavity. Firm, yellow-gray, opaque formations, smooth on the surfaces and measuring 0.2 to 1 cm across, were seen floating in this gelatinous material, which had a golden sheen throughout. As it was impossible to remove all this material by suction, it had to be scooped out by hand and by sponging. Both visceral and parietal peritoneum were studded with firmly adherent, tiny, whitish, seed-like growths, approximately 1 or 2 mm in diameter, which could not be whisked off. The left ovary was identified and found to be normal (the right ovary had previously been removed). The liver could be inspected and was essentially normal except that its undersurface was bound tightly down with adhesions to the transverse colon and omentum. Attached to the right and middle portion of the transverse colon was a multiloculated cystic mass, which apparently lay in the gastrosplenic omentum. The walls of the mass were not intact and showed several openings; they were thin and limp in places, and firm and calcified in others. The patient's condition at this time did not permit any attempt to remove the cystic mass, and the abdomen was closed.

Pathological examination of the pieces of tissue from the cystic mass and from a few peritoneal implants showed them to be composed of an interlacing of connective-tissue fibers and cells in the meshes of which lay structureless basophilic

cium 98 mg, and the phosphorus 2.8 mg per 100 cc. The acid phosphatase was 3.2 King-Armstrong units, and the alkaline phosphatase 2.9 Bodansky units per 100 cc. Occult blood in the feces was shown by the guaiac test. The blood Hinton test was negative.

Seven days after admission a laparotomy was performed. When the abdominal cavity was opened it was found to be filled with gelatinous material that had the same characteristics of that evacuated 1 year before. After removal of this material a multilocular cystic mass was found to surround the hepatic flexure of the colon. The pericolic cystic mass together with the ascending colon and right third of the transverse colon, was resected, and an end-to-end ileocolostomy done with a complementary Weitzel type of catheter ileostomy in the ileum.

Still running a low-grade fever the patient was discharged home for convalescence on the 30th postoperative day.

Pathological examination of the pericolic cystic mass showed it to display a horseshoe shape, one branch of which

FIGURE 1 Cholesterol Crystals and Lime-Salt Deposits in the Gelatinous Exudate within the Abdominal Cavity

material. Mesothelial cells and foreign-body giant cells could be recognized here and there, being especially numerous around cholesterol crystals. No mucus-secreting epithelial cells could be identified. Bacteriologic examination of the intra-abdominal gelatinous exudate failed to reveal the presence of micro-organisms; tubercle bacilli included.

Six months after operation the abdomen began to swell again and when the patient was readmitted, 1 year later, it measured 40 inches in diameter at the level of the umbilicus in the recumbent position; a fluid wave was clearly elicited.

Examination of the blood disclosed a red-cell count of 4,050,000, with a hemoglobin of 15.5 gm per 100 cc., and a white-cell count of 10,450, with a normal differential. Urinalysis showed a specific gravity of 1.005 to 1.015, and albumin from 0 to 110 mg, in different specimens. The sediment was not remarkable except for occasional white and red blood cells. The blood sugar was 80 mg, the nonprotein nitrogen 34 mg, the blood chloride 608 mg, the cholesterol 175 mg, the amylase 13.5 mg, the diastase 33 units, the cal-

FIGURE 2 Inflammatory Reaction at the Site of Crystallized Cholesterol Deposits

measured 12 by 7 by 6 cm and the other 14 by 8 by 7 cm. Both externally and on the cut section the mass consisted of poorly defined, intercommunicating cystic spaces from 0.5 to 2 cm across. Some of the cystic spaces were empty, whereas others contained a gelatinous, yellow-gray material imbedded in which bits of chalk-like, whitish debris were noticeable.

The walls of the cyst, upon microscopical examination appeared to be composed of loosely packed connective-tissue fibers, poor in cells in some areas and rich in cells, mostly fibroblasts, in others. Islands of necrotic fat tissue were noticeable here and there, with disappearance of nuclei and replacement of normal structures by an amorphous basophilic material. Escaped fat globules of different sizes and shapes were noticeable throughout. There was concomitant inflammatory reaction, including granulocytic cell infiltration and proliferation of mononuclear phagocytes. Cholesterol crystals and foam cells were a prominent feature, and giant cells of the foreign-body type were noticeable here and there (Fig. 2). The great majority of the cystic spaces failed to reveal any cellular lining and only occasionally a few regularly aligned tall columnar epithelial cells of the secretory type could be seen (Fig. 3). These cells compared exactly to the lining epithelial cells of the ovarian cyst removed 9 years before (Fig. 4), and no mitotic figures or any other finding pointing to cancerous degeneration could be recognized.

Microscopical examination of the intra-abdominal gelatinous globules showed them to be composed of an outer

The further course of the process depends upon the intrinsic nature and the potentialities of growth of the seeded cells. Cases have been reported in which the process spontaneously regressed through slow reabsorption of the extravasated material. In other cases a peritoneal reaction was found set up around the transplanted mucus and the quiescent epithelial cells, as an attempt, on the part of the organism, to wall off or to engulf the foreign material. Under the same indefinite heading of "pseudomyxoma peritonei" other cases are encountered of true infiltrating cancerous growths, with active proliferation and further dissemination of secreting epithelial cells implanting themselves in the peritoneal surfaces and invading the lymph channels.⁷⁻⁸

The precancerous nature of the mucous membrane of the appendiceal mucocele has been emphasized by Waugh and Findley,⁹ Hentz¹⁰ and Oberndorfer¹¹ have pointed out that a cancerous degeneration may take place in the secretory epithelial cells, poured into the abdominal cavity. According to Woodruff and McDonald¹² there are two kinds of mucocele one, which is underlined by cancerous degeneration of the glandular epithelium, is more apt to lead to the development of pseudomyxoma peritonei, the other, on the contrary, is due to simple obstruction of the appendiceal lumen, retention of secretion and mural dilatation, and it is less likely to give rise to this abdominal complication.

There are recorded cases of pseudomyxoma peritonei developing as late as seventeen years after removal of the original ovarian cyst.¹³ As in the case reported below, the seeded epithelial cells can remain quiescent for many years, still preserving their potentialities of growth and secretion.

It is not within the purpose of this study to enter into the discussion of the mucinous or pseudomucinous nature of the exuded material. An elementary differentiation of mucin and pseudomucin is based on the property of the former to be precipitated by acetic acid. Pseudomucin is said to be alkaline in reaction, and mucin, acidic, hence the former assumes the acid dyes, and the latter the basic dyes. Accordingly, some authors have considered the inner kernel of the gelatinous globule to be a pseudomucin that stains red with eosin, and the outer layer to be a mucin that takes the basic hematoxylin dye. Based on these distinctive characteristics is the conclusion of Fraenkel² and Hughes¹⁴ that the intraperitoneal gelatinous exudate, in connection with ovarian cysts, is a pseudomucin that resulting from a ruptured mucocele is regarded as a mucin. If this could be accepted, the ability to determine the mucinous or pseudomucinous nature of the peritoneal content would be of significant diagnostic value in the cases in which the origin of the process is not clear, but this possibility is disproved by existing data. In 6 of the 142 mucoceles of the appendix examined by Dodge¹⁵ in which the contents were examined, the material appeared to be

a mucin in 3, a pseudomucin in 2 and a colloidal suspension in 1. Phemister¹⁶ also found the secretion obtained from an appendiceal gelatinous cyst to be a pseudomucin. As for the mucinous or pseudomucinous nature of the secretion of the cystic ovarian tumors, the predominant opinion favors Schiller's¹⁷ conclusion that any distinction between the two is not justified, the colloidal phase of the matter being responsible for the differences encountered from case to case.

New aspects in the controversial subject of pseudomyxoma peritonei are offered by the case presented below, inasmuch as it shows that a cholesterol phanerosis can occur in the intra-abdominal gelatinous exudate and that the seeded secreting cells can remain quiescent for many years, still preserving their potentialities of growth and function. As far as we know there are no preceding cases in the literature illustrating the coexistence of a cholesterous and mucinoid effusion.

CASE REPORT

A 75-year-old woman was first admitted to this hospital on March 16, 1947, with the chief complaint of abdominal pain and loss of weight.

Nine years previously a twisted right ovarian cyst of the "pseudomucinous" type had been removed at another hospital. At that time the appendix was also removed and found to be normal. After this operation the patient felt well for about 3 years and then began to suffer from upper abdominal distress, which was attributed to a diaphragmatic hernia. For the past 2 years the appetite had been poor, and she had lost 30 pounds in weight. She had always been constipated, but no bloody, tarry or acholic stools had been noticed at any time. For the past 2 months she had begun to notice a sharp, nonradiating painful sensation in the right lower abdomen, which occurred every week or so and lasted 10 to 15 minutes.

Physical examination revealed a chronically ill, elderly woman. The abdomen was distended, with a shifting dullness, and a fluid wave could be elicited. The liver edge was not felt, and no abnormal masses could be palpated in the abdominal cavity.

The temperature, pulse and respirations were within normal limits. The blood pressure was 165 systolic, 75 diastolic.

Examination of the blood showed a red-cell count of 3,250,000, with a hemoglobin of 10.5 gm per 100 cc., and a white-cell count of 7000, with 72 per cent neutrophils, 24 per cent lymphocytes, 1 per cent monocytes and 3 per cent eosinophils. Urinalysis was insignificant except for a persistent low specific gravity (1.007 to 1.010). The blood sugar was 87 mg., the nonprotein nitrogen 20 mg., and the total protein 6 gm. per 100 cc., the blood amylase was 12 units per 100 cc. Occult blood in the stools was shown on several occasions by a guaiac test. The cephalin-flocculation and blood Hinton tests were negative.

X-ray studies revealed a congenital shortening of the esophagus, with herniation of about half the stomach into the thorax, through the esophageal orifice of the diaphragm. A large, lobulated, ring-like area of calcific density was noticeable in the right middle portion of the abdomen anteriorly. This shadow was believed to be consistent with the presence of a calcified mesenteric cyst or similar type of intrinsic abdominal mass.

A peritoneoscopy was performed, but owing to the presence of an enormous quantity of gray-yellow gelatinous material in the abdominal cavity none of the organs or the peritoneal surfaces could be clearly visualized.

Pathological examination of a few nubbins of yellowish, firm tissue obtained at peritoneoscopy, showed a structureless basophilic material imbedded in which lay abundant cholesterol crystals and lime-salt deposits (Fig. 1).

several years previously had had an operation for empyema

The etiology of the process is not clear. In about 50 per cent of the cases pulmonary tuberculosis co-existed.²¹ Diabetes or syphilis or a combination of these with tuberculosis has sometimes been considered a causal factor. Even though tubercle bacilli could not be demonstrated in many cases Erwin²⁰ has expressed the opinion that by virtue of chronicity, tuberculosis is the disorder most calculated to evoke such cholesterosis and that there is a reason to suspect a tuberculous basis in most of the published cases of cholesterous pleural effusion.

Protracted exudation, tendency to sequestration of the exudate, progressive thickening of the enclosing membrane and consequent delay in the normal process of reabsorption provide the pleural space with the conditions most favorable for the development of the process. It is not, however, the only location in which cholesterol crystallization has been recorded in association with an exudative process. Bignami²² has found a comparable situation in a case of hydrocele (cholesterinic hydrocele), Fabris²⁴ in a case of pyonephrosis (cholesterinic pyonephrosis), and Lugo²⁵ within a cyst in the subdural space. Effusions of cardiac and renal origin are, in general, terminal complications of the underlying disease. Therefore, they seldom provide the conditions necessary to cholesterol deposition, nevertheless a few cases exemplifying this possibility have been reported.

Regardless of the location, the genetic mechanism of the process is apt to be the same in all cases. As for the source of the cholesterol in the exudate, a number of investigators have suggested a hematic origin.²⁰ Against this as the only source is the normality of cholesterol blood levels in the great majority of the reported cases (our own included), the higher cholesterol content of the exudate as compared to that of the blood itself and the fact that the progressive thickening of the enclosing membranes obviously embarrasses any interchange between the constituents of the circulating body fluids and the constituents of the exudate. This has been proved by an experiment by Bever²⁶. He added sodium salicylate to the pleural space of patients with cholesterinic pleurisy and noticed a marked slowing down in the urinary elimination of the introduced substance as compared to that occurring after injection of the same chemical in a simple serous pleurisy.

The possibility of a synthetic origin of the cholesterol from the exudate itself has been suggested by Barbier and Tricaud,²⁷⁻²⁸ who noticed increase of the cholesterinic content in the fluid extracted from a patient with cholesterol pleurisy, but this has not been confirmed.²⁶ A participation of the corpusculated elements of the exudate in the formation of the cholesterol in the presence of proteolytic enzymes splitting the ¹¹⁻¹² proteins has also been consid-

ered. The amount of cholesterol contributed in this fashion is not sufficient, however, to account for the high cholesterinic content of the exudate. There are in addition, recorded cases in which no cellularity was demonstrable in the exudate.

The tendency of the necrotic tissues to draw lime salts and neutral fats is well known, it might not be surprising, therefore, that the damaged tissues themselves enclosing the exudate would provide the conditions necessary to attract the cholesterol circulating in the body fluids and to provide additional cholesterol through the desquamation and melting in the exudate of degenerated cellular elements.

It is most likely that the cholesterol in the exudate derives from different sources including the blood stream, the corpusculated elements in the exudate and the membrane enclosing the exudate itself, each of these various sources or a combination of them playing the main role in the different cases. This conclusion also applies to the case reported above.

As for the conditions leading to the crystallization of the cholesterol in the exudate, it has been thought that the phenomenon is related to a rupture of the chemical physical balance of the constituents and that whenever the cholesterol reaches a critical concentration, crystallization occurs. Against this view is the absence of any quantitative relation between the free or combined cholesterinic fraction and the fraction of crystallized cholesterol.

Desbordes and Levy²⁹⁻³⁰ have shown that as effusions in the body cavities become old the total protein remains constant but an inversion occurs in the albumin-globulin ratio, and this is accompanied by a decrease of the cholesterolytic power of the fluid. This observation is in agreement with the results of the experiments of Mauriac³¹ showing inversion of the albumin-globulin ratio to the advantage of the globulins without notable lowering of proteins, in rabbits with induced hypercholesteremia. It seems, therefore, that a part of the cholesterol exists in the state of a "complex" associated with the albumin-globulin combination, this liaison being apparently related to the globulin and the albumin contributing to the holding in solution of the cholesterol.

All this has been advocated by Erwin²⁰ to explain the presence of crystallized cholesterol in his case of pleural effusion "as the fluid ages the globulin increases, the albumin decreases and a cholesterol phanerosis develops in the form of crystals giving the golden-sheen observed in several of the reported cases."

The same explanation can be advanced for the case reported above. Protracted exudation and progressive thickening of the enclosing membranes provided the ideal conditions to prevent the reabsorption of the exuded material and the interchange of constituents with the constituents of the circulating body fluids, hence the disruption in the albumin-

basophilic staining laminated hull and of an eosinophilic center, which consisted of finely granular material with occasional cholesterol crystals

Chemical analysis of the abdominal fluid, 8 liters in amount, was performed. A trace of nucleoproteins was obtained by

FIGURE 3 Regularly Aligned Secretory Epithelium in a Peritoneal Implant, Exactly Reproducing That Seen in Figure 4

the acetic acid test, as well as by the Almen reagent, after heat treatment of the fluid to remove coagulated protein. However, a qualitative test for phosphorus on the coagulated protein was positive, indicating possibly that some of the nucleoproteins had been precipitated by heating to 100°C. The fluid had a total cholesterol of 229 mg, total phospho-

FIGURE 4 Pseudomucinous Cyst Removed Nine Years before Admission

lipids of 62.5 mg, total lipoid fatty acids of 134 mg and neutral fat of 27 mg per 100 cc.

Bacteriologic examination revealed *Escherichia coli*.

The peritoneal cavities of 2 guinea pigs and 6 white mice were injected with 0.5 and 0.3 cc, respectively, of an emulsion of the abdominal exudate. All the animals remained healthy, and when they were killed, from 2 to 4 months after inoculation, no traces of the injected material or any visible tissue reaction could be found.

DISCUSSION

In the case reported above as in many comparable cases in the literature, the origin of the gelatinous exudate in the peritoneal cavity could be traced to a "pseudomucinous" ovarian cyst.

Nine years occurred between the removal of the ovarian cyst and the second operation. This shows that the seeded epithelial cells can remain quiescent for many years, still preserving their potentialities of growth and function.

To judge from the amazing amount of accumulated secretion evacuated from the abdominal cavity when the condition was first detected (from 6 to 7 liters) and by the promptness with which the abdomen filled up again within the year, with an additional 8 liters of similar material, one would have expected to find extensive seeding of secreting epithelial cells in the peritoneal surfaces. Instead, no secretory epithelium could be detected in the pieces of tissue removed at exploratory laparotomy, and only after many blocks of tissue had been cut through were a few cells with these characteristics seen in the removed pericolic cystic mass.

The failure to reproduce the condition in mice and guinea pigs after intraperitoneal inoculation of particles of the exudate is perhaps best explained on the basis of the paucity of secreting epithelium. A singular aspect was the presence of huge amounts of cholesterol crystals in the peritoneal exudate and in the enclosing peritoneal membranes.

Cholesterous effusions have been described in a variety of conditions, but except for a short account in the paper of Probst and Lassar¹⁸ on cholesterol crystal inclusions within the gelatinous globules in a case of appendiceal myxoglobulosis, no mention could be found of a similar condition in any of the reported cases of pseudomyxoma peritonei.

Churton,¹⁹ in 1892, is credited with the first description of a chronic pleural effusion characterized by the presence of cholesterol crystals. In 1941 Erwin²⁰ found 30 similar cases recorded, and since then only a case by Evander²¹ has been added to this meager series. In practically all reported cases there was a history of long-standing effusion, showing little tendency to spontaneous reabsorption and repeatedly recurring after evacuation. The fluid, as a rule alkaline in reaction, was variously described as clear or turbid, with a color ranging from light yellow or brown to dark red. In some cases a few inflammatory cells, or fragments of cells, were seen. In others several hundred cells were present. The fluid was usually encysted by firm, fibrous bands, and the pleural surfaces were greatly thickened. In all cases the recognition of the process depended entirely upon the accidental discovery of the polyhedral cholesterol crystals in the absence of clinical symptoms or signs that might have made one aware or suspicious of the existing condition. Nearly all patients were middle-aged men, only a report by Sharpe²² deals with a nine-year-old who

several years previously had had an operation for empyema

The etiology of the process is not clear. In about 50 per cent of the cases pulmonary tuberculosis co-existed.²¹ Diabetes or syphilis or a combination of these with tuberculosis has sometimes been considered a causal factor. Even though tubercle bacilli could not be demonstrated in many cases Erwin²⁰ has expressed the opinion that by virtue of chronicity, tuberculosis is the disorder most calculated to evoke such cholesterosis and that there is a reason to suspect a tuberculous basis in most of the published cases of cholesterous pleural effusion.

Protracted exudation, tendency to sequestration of the exudate, progressive thickening of the enclosing membrane and consequent delay in the normal process of reabsorption provide the pleural space with the conditions most favorable for the development of the process. It is not, however, the only location in which cholesterol crystallization has been recorded in association with an exudative process. Bignami²² has found a comparable situation in a case of hydrocele (cholesterinic hydrocele), Fabris²⁴ in a case of pyonephrosis (cholesterinic pyonephrosis), and Lugo²⁵ within a cyst in the subdural space. Effusions of cardiac and renal origin are, in general, terminal complications of the underlying disease. Therefore, they seldom provide the conditions necessary to cholesterol deposition, nevertheless a few cases exemplifying this possibility have been reported.

Regardless of the location, the genetic mechanism of the process is apt to be the same in all cases. As for the source of the cholesterol in the exudate, a number of investigators have suggested a hematic origin.²⁰ Against this as the only source is the normality of cholesterol blood levels in the great majority of the reported cases (our own included), the higher cholesterol content of the exudate as compared to that of the blood itself and the fact that the progressive thickening of the enclosing membranes obviously embarrasses any interchange between the constituents of the circulating body fluids and the constituents of the exudate. This has been proved by an experiment by Bever²⁶. He added sodium salicylate to the pleural space of patients with cholesterinic pleurisy and noticed a marked slowing down in the urinary elimination of the introduced substance, as compared to that occurring after injection of the same chemical in a simple serous pleurisy.

The possibility of a synthetic origin of the cholesterol from the exudate itself has been suggested by Barbier and Tricaud,²⁷⁻²⁸ who noticed increase of the cholesterinic content in the fluid extracted from a patient with cholesterol pleurisy, but this has not been confirmed.²⁶ A participation of the corpusculated elements of the exudate in the formation of the cholesterol in the presence of proteolytic enzymes splitting the cellular proteins has also been consid-

ered, the amount of cholesterol contributed in this fashion is not sufficient, however, to account for the high cholesterinic content of the exudate. There are, in addition, recorded cases in which no cellularity was demonstrable in the exudate.

The tendency of the necrotic tissues to draw lime salts and neutral fats is well known, it might not be surprising, therefore, that the damaged tissues themselves enclosing the exudate would provide the conditions necessary to attract the cholesterol circulating in the body fluids and to provide additional cholesterol through the desquamation and melting in the exudate of degenerated cellular elements.

It is most likely that the cholesterol in the exudate derives from different sources including the blood stream, the corpusculated elements in the exudate and the membrane enclosing the exudate itself, each of these various sources or a combination of them playing the main role in the different cases. This conclusion also applies to the case reported above.

As for the conditions leading to the crystallization of the cholesterol in the exudate, it has been thought that the phenomenon is related to a rupture of the chemical physical balance of the constituents and that whenever the cholesterol reaches a critical concentration, crystallization occurs. Against this view is the absence of any quantitative relation between the free or combined cholesterinic fraction and the fraction of crystallized cholesterol.

Desbordes and Levy²⁹⁻³⁰ have shown that as effusions in the body cavities become old the total protein remains constant but an inversion occurs in the albumin-globulin ratio, and this is accompanied by a decrease of the cholesterolytic power of the fluid. This observation is in agreement with the results of the experiments of Mauriac³¹ showing inversion of the albumin-globulin ratio to the advantage of the globulins, without notable lowering of proteins, in rabbits with induced hypercholesteremia. It seems, therefore, that a part of the cholesterol exists in the state of a "complex" associated with the albumin-globulin combination, this liaison being apparently related to the globulin and the albumin contributing to the holding in solution of the cholesterol.

All this has been advocated by Erwin²⁰ to explain the presence of crystallized cholesterol in his case of pleural effusion "as the fluid ages the globulin increases, the albumin decreases and a cholesterol phanerosis develops in the form of crystals giving the golden-sheen observed in several of the reported cases."

The same explanation can be advanced for the case reported above. Protracted exudation and progressive thickening of the enclosing membranes provided the ideal conditions to prevent the reabsorption of the exuded material and the interchange of constituents with the constituents of the circulating body fluids, hence the disruption in the albumin-

globulin liaison, which normally contributes to the holding in solution of the cholesterol, followed by its precipitation and formation of the characteristic rhomboidal crystals

SUMMARY

A case of "pseudomyxoma peritonei," most unusual for the presence of large deposits of cholesterol crystals in the exudate, is presented. Protracted exudation and progressive thickening of the enclosing membranes, interfering on one side with the reabsorption of the exuded matter and on the other with the interchange of its constituents with the constituents of the circulating body fluids, are advanced to explain this cholesterol phanerosis. The origin of the process could be traced to a "pseudomucinous" cystadenoma of the ovary removed nine years before. The long period intercurring between the removal of the cyst and the development of the abdominal condition shows that the seeded epithelial cells can remain quiescent for many years, still preserving their potentialities of growth and function.

VENTRICULAR STRAIN AND VENTRICULAR HYPERTROPHY*

DAVID LITTMANN, M D †

WEST ROXBURY, MASSACHUSETTS

WHEN medical terminology was less precise the expression "strained heart" was employed at times to describe obscurely but ominously diseased hearts. This diagnosis is no longer made, but currently the terms heart strain and ventricular strain are occasionally used to identify electrocardiographic patterns encountered in various types of heart disease.¹ The dictionary defines strain as "the hurt or injury from excessive tension or use, as of muscles, nerves and organs, deformation or distortion due to stress or force, stretched beyond its proper limits." Stress is "the force, pressure or influence impinging upon or acting against the member or organ under consideration."

The heart is normally subjected to stresses against which it operates to perform its work. In the absence of myocardial disease these are adequately countered without injury or strain. Furthermore, the reserve capacity of the normal heart enables it to cope successfully with greatly increased stresses as during excitement, violent exercise, anemia, pregnancy and infection. In a like manner, patients with moderate hypertension, valvular insufficiency or chronic pulmonary disease may go for many years without any evidence or symptoms of cardiac involvement. However, if the stresses exceed physiologic reserves, strain occurs, which may be acute, as in pulmonary embolism, or chronic, as in important hypertension. These become objectively manifest as dilatation and, if the condition is chronic, dilatation and hypertrophy (distortion). This stage may or may not be accompanied by symptoms. Strain may occur with an essentially normal myocardium. On the other hand, disease of heart muscle renders the heart less capable of coping with normal physiologic stresses. In either event strain represents a state of imbalance. It should be apparent that although it is usually the result of organic disease, heart strain is actually a functional disorder that is often reversible.

Although the term heart strain should not properly be applied to an electromechanical tracing, specific electrocardiographic patterns are encountered either as the result of or occurring coincident with the cardiac "hurt or injury" of ventricular strain. The exact cause for the observed abnormalities is obscure. They may somehow be related to mechanical stretching or distortion of the myocardium or to more subtle alteration of the metabolic processes. In either event they are limited almost wholly to the

repolarization process and result in depressions of the ST segment and T-wave inversions.

In 1935 the electrocardiographic findings in acute pulmonary embolizations were described.² These consisted of the development of an S wave in Lead I and a Q wave in Lead 3 and of deviations in the ST segments in Lead I and 3. There were also T-wave inversions in L_{III} and L_{IV} . Later studies indicated that the S wave in Lead I and Q wave in Lead 3 were manifestations of cardiac rotation and not of myocardial distress. Clockwise rotation of the heart on its long axis was also observed as shown by development of S waves in the leads from the left side of the chest. Inversion of the precordial T waves was, apparently, the only valid evidence of heart strain and was limited to leads obtained over or derived from the right ventricle. In some cases of chronic cor pulmonale resulting from persistent pulmonary hypertension, considerable right ventricular hypertrophy occurs, and in addition to the electrocardiographic findings noted in the acute form the R waves in the right precordial leads become prominent and the S waves small.^{3,5}

It is apparent, therefore, that uncomplicated strain of the right ventricle results in ST-segment and T-wave changes in the leads from the right precordium, whereas right ventricular hypertrophy produces alterations in the QRS complexes. For the sake of completeness it is well to note that other electrocardiographic forms are encountered in right ventricular disease. For example, the electrocardiogram may be entirely normal in both acute and chronic cor pulmonale. Chronic strain of the right side of the heart with moderate hypertrophy may result in an electrocardiographic pattern that is indistinguishable from acute strain, and both resemble the findings commonly seen in children and in some adult Negroes. Partial or complete right-bundle-branch block is sometimes found in both acute and chronic cor pulmonale but appears also in coronary-artery disease.

Investigators are in agreement regarding the electrocardiographic criteria that may be used to distinguish right ventricular strain (Fig 1) from right ventricular hypertrophy (Fig 2). The agreement is not quite complete, however, with left ventricular disease. The term left "heart strain" has now been largely replaced by "hypertrophy." This may be because "strain" has obscure implications whereas "hypertrophy" is obvious and can be co-ordinated with physical, x-ray and autopsy findings. Furthermore regardless of its exact meaning, strain of the left ventricle is almost always accompanied by hypertrophy.

†Cardiologist, Veterans Administration Hospital.

From an electrocardiographic point of view, there is, unfortunately, no clinical state involving the systemic circulation quite comparable to that which obtains in the lesser system after extensive pulmonary embolization. A somewhat similar situation might arise during the hypertensive crisis of pheochromocytoma. However, few striking electrocardiographic changes are encountered here, possibly because the left ventricle is better able to handle acute insults than the right. Nevertheless, it appears probable that strain of the left ventricle occurs in other situations and that it results in a distinguishable electrocardiographic picture.

The pattern of left ventricular hypertrophy has recently been reviewed and more carefully defined.^{3,4,6} It is considered to be present when the QRS complexes from the left side of the precordium (V_1 or V_4 or both) consist largely or entirely of R waves of unusual height and duration (greater than 27 mm in height, with intrinsic deflection of 0.04 second or more after the origin) or when the sum of S in V_1 and R_1 exceeds 35 mm (See Fig 6). Commonly, these changes are also accompanied by a depressed or sloping ST segment and an inverted T wave in Lead V_1 or V_4 (See Fig 7). Usually, the heart is horizontal, but the same changes may occur with the heart in the intermediate or even in the

may be reversible. As a corollary it is likely that the second indicates hypertrophy without coincident strain.

In support of these contentions a series of clinical situations is submitted for consideration. In some of these, electrocardiographic patterns similar to hypertrophy (ST-segment and T-wave changes but R waves of ordinary amplitude) were observed to develop acutely or to disappear. The time consumed was brief, and there were no measurable differences in heart size. In another group of pa-

normal vertical position. Although this is the commonly accepted electrocardiographic pattern of left ventricular hypertrophy there are important exceptions. Electrocardiograms are seen that fulfill the ST-segment and T-wave requirements without having R and S waves of abnormal size. Contrariwise, an occasional record is encountered with R and S waves of heroic proportions but with ST segments and T waves that are normal. It is suggested that the first of these variants represents, in fact, left ventricular strain without hypertrophy and that it

tients a similar electrocardiographic picture was present in spite of the absence of hypertrophy, hypertension or valvular disease.

HYPERTROPHY-LIKE PATTERN WITH HYPERTENSION OR VALVULAR DISEASE

A left hypertrophy-like pattern has been observed in patients with hypertension or aortic-valve disease and congestive failure upon recovery of compensation. Occasionally, patients in congestive (right ventricular) failure secondary to left failure resulting from hypertension or aortic-valve disease demonstrate normal electrocardiograms. However, upon recovery electrocardiographic findings resembling left ventricular hypertrophy become apparent in days to weeks. The following case is used to illustrate this phenomenon.

CASE 1 A 69-year-old former laborer, with a past history including hypertension, thrombophlebitis and pulmonary embolism, was admitted to the hospital because of weakness and evidence of myocardial failure. There was extensive cerebral arteriosclerosis and senility. Physical examination revealed a heart that was at the outer limits of normal in size (confirmed by x-ray study), pulmonary moisture and extensive edema of the legs and thighs. The blood pressure was 180/110. The electrocardiogram on admission was essentially normal (Fig 3A). He responded well to treatment of his

cardiac failure with clearing of both the pulmonary and peripheral edema. At this time the electrocardiogram developed findings resembling those of left ventricular hypertrophy with ST-segment and T-wave changes but R waves of normal amplitude (Fig 3B). In spite of cardiac improve-

FIGURE 3 Electrocardiograms in Case 1

ment decubitus ulcers developed, and the patient died, apparently of sepsis. Permission for autopsy was not obtained.

HYPERTROPHY-LIKE PATTERN WITHOUT HYPERTENSION, HYPERTROPHY OR VALVULAR DISEASE

The situation in which a left hypertrophy-like pattern is present has been observed with consider-

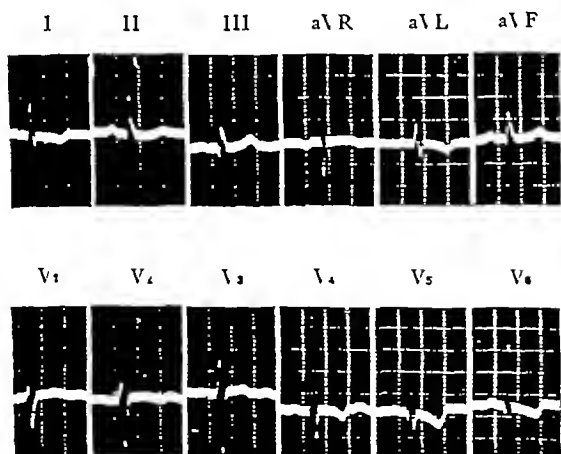

FIGURE 4 The Pattern of Left Ventricular Strain without Hypertrophy (Case 2)

able frequency in patients with angina pectoris but no hypertension, hypertrophy or valvular disease. The following case illustrates this situation.

CASE 2 A 58-year-old storekeeper was admitted to the hospital with complaints of rectal bleeding and retrosternal distress related to cold weather and effort. There were no symptoms of myocardial insufficiency. The bleeding was found to result from benign rectal polyps. Examination of the heart revealed it to be of normal size, and the rhythm was regular. There was a soft systolic apical murmur. The aortic second sound was greater than the pulmonic. The blood pressure was 130/70. X-ray study of the chest showed a heart of normal shape and size. The transverse diameter of the heart was 14 cm and the internal diameter of the chest was 31 cm. The angina was easily controlled with nitroglycerin. The electrocardiogram (Fig 4) was similar to that in Case 1.

HYPERTROPHY-LIKE PATTERN IN ANGINA DECUBITUS

The development of an electrocardiographic pattern resembling that of left hypertrophy during the course of angina decubitus is a rarely encountered phenomenon that may be found in the absence of hypertrophy, hypertension and so forth. It may

FIGURE 5 Electrocardiograms in Case 3

On admission the record is normal except for evidence of digitalis (A). Five days later during a period of angina decubitus, there are sloping ST segments and inverted T waves in Lead I, 2 and 3 (B). Three months later, the electrocardiogram is within normal limits (C).

occur in a few days and has been noted to disappear together with improvement in the clinical state.

The following case is typical of those in this group.

CASE 3 A 56-year-old government employee had been aware of retrosternal pain on effort for 3½ years. This gradually increased in frequency and severity, and 3 weeks before admission the patient could walk only 1 block without pain. Two days prior to entry pain began to occur at rest and became almost continuous. This was barely relieved by nitroglycerin and digitalis supplied by his family physician. The patient was an obese white man who showed the slightest possible trace of ankle edema. However, there was no dyspnea or orthopnea. On x-ray examination the heart was just within normal limits of size. The transverse diameter of the heart was 15 cm, and the internal diameter of the chest was 31 cm. The heart was in the horizontal position. It was narrow waisted and of normal area. The blood pressure was 152/92.

From an electrocardiographic point of view, there is, unfortunately, no clinical state involving the systemic circulation quite comparable to that which obtains in the lesser system after extensive pulmonary embolization. A somewhat similar situation might arise during the hypertensive crisis of pheochromocytoma. However, few striking electrocardiographic changes are encountered here, possibly because the left ventricle is better able to handle acute insults than the right. Nevertheless, it appears probable that strain of the left ventricle occurs in other situations and that it results in a distinguishable electrocardiographic picture.

5B). Three months after admission, when the patient was essentially free of complaints, the electrocardiogram was again normal (Fig 5C).

DISCUSSION

The cases used above to illustrate the development and recession of an electrocardiographic pattern are obviously unusual. Cardiologists are much more familiar with patients in comparable clinical situations who have not shown similar changes. However, these differences can be reconciled. Generally, patients with sufficient hypertensive disease to result in congestive failure have well marked hypertrophy patterns (Fig 7), which cannot be expected to alter greatly. In a like manner patients with angina decubitus ordinarily have enough coronary-artery disease to result in grossly abnormal electrocardiograms, which ordinarily change only to become worse. One can expect rapid and significant development, therefore, only in the rare cases in which the tracings are still essentially normal but delicately balanced and in which little additional strain is required to precipitate electrocardiographic evidence of this phenomenon.

The following explanation is offered to account for the presence of the electrocardiographic pattern resembling that of left hypertrophy in the clinical states described above.

In the cases of congestive (right ventricular) failure secondary to disease of the left ventricle the presence of a heart-strain pattern prior to decompensation has not been proved. It may or may not have been present. Most observers are in agreement that cardiac output is either absolutely or relatively diminished during such failure. It follows naturally that the work of the left ventricle is proportionately lessened and that the left ventricle is temporarily relieved of its customarily increased stress. Accordingly, the strain of the left side of the heart is similarly partly or completely alleviated, and the electrocardiogram may be normal. Upon recovery of compensation, however, the left ventricular output and work increase, and with these there is electrocardiographic evidence of strain. This sequence of events is reminiscent of a somewhat similar phenomenon observed in patients with angina pectoris who

FIGURE 7 Left Ventricular Hypertrophy and Strain in a Patient with Hypertensive Heart Disease and Marked Cardiac Hypertrophy

Note the prominent R waves sloping and bowed ST segments and inverted T waves in Lead I and aVL (RaVL 1.9 mV), deep S wave in Lead I₂ (2.5 mV, trough off record as shown), tall R waves in Lead I₃ (3 mV, peak off record) and depressed, bowed ST segments and inverted T waves in the left precordial leads.

develop congestive failure. Commonly, the angina wanes with the onset of decompensation. It reappears with recovery from failure probably because of the simultaneously increased output and work of the left ventricle.

In angina pectoris the presence of abnormal left ventricular physiology is clear. Here the often extensive coronary-artery insufficiency results in an ischemic and diseased myocardium that is unable to cope with normal stresses (angina decubitus) or moderately increased stresses (angina of effort), and strain ensues.

The frequency of the electrocardiographic pattern of ST-segment and T-wave abnormalities in Lead

V_4 and V_6 in patients with angina but without hypertrophy is too great to be wholly fortuitous. Some cardiologists, in fact, prefer to interpret such findings as "consistent with coronary-artery disease."

In Case 3 described above the strain pattern developed during a period of critical coronary-artery inadequacy. Subsequently, after all pain had disappeared, the electrocardiogram became normal. It is highly improbable that myocardial hypertrophy developed in six days and then disappeared. It is thought that during a period of grave coronary insufficiency the heart was unable to meet its basal physiologic requirements and was strained by normal stresses. This was accompanied by an electrocardiographic pattern thought to indicate left ventricular strain. When an adequate collateral circulation became available the enhanced ability of the heart to perform its work led to both clinical and electrocardiographic improvement. Unfortunately, such close parallels between clinical and electrocardiographic states are rarely encountered.

The pattern of depressed or sloping ST segments and inverted T waves but without abnormally prominent R waves in the outer (left) precordial leads is taken as the electrocardiographic manifestation of left ventricular strain without hypertrophy. This may be reversible. When unusually prominent R waves are also present, hypertrophy and strain coexist. One phenomenon that has not thus far been considered is the lowering of ST segments and T waves resulting from a simple enlargement of the R waves in hypertrophy. Although this is a real influence it presently remains an uncertain and, in any one case, an unmeasurable factor. The ventricular gradient, which is customarily normal in left ventricular hypertrophy, is computed from the limb leads. This discussion primarily concerns the precordial phenomena. These have been shown to differ widely at times from those derived from the limbs. The findings in hypertrophy are ordinarily permanent except when cardiac enlargement can be reduced. This sometimes occurs after sympathectomy in hypertensive patients.

One may, accordingly, conceive of the pattern of left ventricular strain as electrocardiographic evidence of the unphysiologic state that obtains with left ventricular inability to cope with normal or abnormal stresses. In this manner it is possible to account for the occasional appearance of an electrocardiographic picture not grossly dissimilar from that of left hypertrophy in patients without cardiac

enlargement. Such persons generally have coronary-artery insufficiency or intrinsic myocardial disease.

SUMMARY

Ventricular strain is a pathologic state of imbalance that occurs with myocardial inability to contend with normal or abnormal stresses. It may cause reversible electrocardiographic alterations.

Right ventricular strain due to abnormal stress is commonly seen with acutely or chronically elevated pulmonary pressures. Isolated strain of the left side of the heart occurs in coronary-artery inadequacy because of diminished ventricular ability to cope with normal stresses.

Aside from changes due to cardiac rotation, right ventricular strain becomes manifest electrocardiographically by ST-segment and T-wave changes in the right ventricular precordial leads. When significant (probably great) hypertrophy is added, the R waves in the same leads become abnormally tall and broad, whereas the S waves diminish in size.

An electrocardiographic picture superficially resembling that found in left hypertrophy has been observed to develop from apparently normal records in patients with left ventricular disease recovering from congestive failure. It is seen in others who have no cardiac enlargement. The same pattern has also been seen to emerge in patients with rapidly increasing angina pectoris and to clear with clinical improvement.

Observations in these clinical states suggest that distinguishing differences can be noted between strain and hypertrophy of the left ventricle similar to those on the right side.

The ST-segment and T-wave abnormalities in precordial Lead V_4 or V_6 , or both, are considered to be manifestations of left ventricular strain. Enlargement of the R waves in the same leads constitutes evidence of left ventricular hypertrophy. These are usually seen together but may occur separately.

CONDITIONED-REFLEX TREATMENT OF ALCOHOLISM

I Its Rationale and Technic*

JOSEPH THIMANN, M D †

BOSTON

FEBRUARY, 1949, marked the end of seven years of application of the conditioned reflex as a therapy for alcohol addiction at the Washingtonian Hospital. This fact calls for an evaluation of this part of the total therapeutic plan^{1, 2} concerning chronic alcoholism.

The present article is the first of two dealing with the rationale, technic, indications, contraindications, risks and psychologic aspects of the treatment, as well as its efficacy and methods of evaluating it.

The last two decades have made it quite fashionable for any intelligent lay person, and a veritable shibboleth for a modern professional man, to announce that alcoholism is a disease and that alcoholic patients are sick people. The professional and lay therapist alike consider it necessary to aim at one target—the underlying cause of the patient's addiction. Focusing on this, they analyze the patient for old and recent traumas and try to determine how far these traumas have initiated a discouraging or frustrating mechanism. An attempt, then, at eliminating the neurotic defense mechanisms and building new constructive patterns of life is considered to constitute the treatment of addiction.

Unfortunately, the majority of alcohol addicts continue to relapse even after psychotherapy of one kind or another.

Careful observations of large numbers of patients have confirmed the impression that the psychopathology of alcohol addiction resembles, in certain aspects, that of addiction to narcotics. If a person suffering from gallstones is given morphine for a certain length of time and happens to be predisposed to addiction, the addiction will develop. In such a case it is agreed that removal of the gall bladder will in most cases eliminate the pain, but not the addiction to morphine. By then, the addiction will have developed into an autonomous disease, independent of whether the underlying cause, the gallstone colic, still exists or has been removed. I think that there is reason to assume that the uncontrollable desire for alcoholic beverages is governed by similar laws. It may, of course, be precipitated by an underlying neurosis or some combination of inner and outer factors. From the point at which the addictive pattern has become established, however, it is as autonomous as morphine addiction. From then on the addict does not drink because of his neurosis or whatever has caused his addiction, he does not even drink, as a physician

once put it, "in order to get drunk." He drinks because he is addicted, because the established addiction is self-perpetuating and causes the compulsive need for more and more alcohol. Thus, the impulse for alcohol can best be described as an abnormal conditioned reflex.

If this theory is accepted as a working hypothesis, one will not expect many alcohol addicts to stop drinking after undergoing psychoanalysis or some other psychotherapy without specific treatment for the addiction as such, just as morphine addicts are not expected to give up morphine because the underlying gall-bladder disease and pain have been eliminated. Accepting this hypothesis of the autonomous character of the alcohol compulsion as such does not, of course, mean underrating the importance of psychotherapy in the treatment of the underlying personality disorder, either the primary one, existing in the prealcoholic personality, or the secondary neurosis, which may have developed as a result of the feelings of helplessness, guilt or inferiority incident to the addiction.

The idea of outweighing the craving for alcohol by means of a revulsion established artificially against it is at least as old as Pliny the Elder, who in his *Historiae Naturalis*³ lists quite a few, (somewhat naïve) methods. Beginning in 1930, several European therapists,^{4, 7} among them Dent⁸ in England, reported their experiments in establishing a conditioned reflex against alcoholic impulses.¹ In this country Fleming,⁹ of Boston, seems to have been the first to apply Dent's technic of apomorphine injections to 36 patients, with an estimated success of 35 per cent.

The first reports about highly successful treatment of a large number of alcoholic patients, with subsequent observation over a period of more than four years, emanated from the Shadel Sanitarium in Seattle, Washington,^{10, 12} from 1940 to 1942, an average of 64.3 per cent of total abstinence from alcoholic beverages† among patients treated being claimed. The authors reported the use of a 7.8 per cent solution of emetine, supplemented by pilocarpine and ephedrine as the unconditioned stimulus, the alcoholic beverages constituting the conditioned one. Emetine appeared more appropriate than apomorphine, which was used by Dent, because it caused the desired prolonged nausea and because it lacked the disturbing euphoric and hypnotic after-effects. Several simultaneous exposures to the un-

*These articles represent abstracts from a book that is in the process of being prepared for publication.

†Medical director, Washingtonian Hospital.

‡A recent report from the same institution claims a 44.8 per cent efficacy in an observation period of ten and a half years.¹³

conditioned and conditioned stimuli entailed a reflex association between both. Whether this association developed to the extent of an active and conscious revulsion to and nausea at the sight, taste, smell and even thought of alcoholic beverages, as it usually does shortly after its establishment, or whether it merely developed to the extent of outweighing the compulsive reach for a drink, depends on the technic and — it seems to me — also on the patient's personality. Pavlov already knew that conditioned reflexes are apt to "fade out" if they are exposed for a certain length of time to the conditioned stimulus only, without the reinforcing action of a simultaneous unconditioned stimulus. To prevent the treatment from losing its efficacy, the initial series was followed up by additional sessions (reinforcements), given in intervals during the first year.

Seven years ago, the conditioned-reflex therapy was started at the Washingtonian Hospital.¹⁴ It was modified in technic to increase its efficacy. Furthermore, it was supplemented by methodic psychotherapy and part-time hospitalization,¹⁵ as well as by manipulation of the patient's environment. This included case work with relatives, whenever these measures seemed indicated. Group therapy was organized in the form of semimonthly meetings of the hospital abstinence club comprising all patients who "graduated" from the initial series of the conditioned-reflex therapy. The term "part-time hospitalization" describes an arrangement that combines the advantages of a protective environment with those of the exposure to the unsupervised, normal environment. These patients work full time at their regular place of work, but spend their free time in the hospital. The period of hospitalization is gradually reduced, thus, the patient becomes increasingly able to handle in a mature way all the usual daily problems of an adult.

It may be appropriate to describe here one conditioning session as given at the Washingtonian Hospital.

The treatment room should be arranged in such a way as to eliminate all distracting stimuli.¹⁴ The treatments are given in the morning, because patients react better when fasting and rested. The preliminary medication consists of 10 to 20 mg of Benzedrine sulfate and 1 mg of strychnine sulfate followed by a capsule containing 0.06 to 0.15 gm (60 to 150 mg) of emetine hydrochloride with 1 to 3 glasses of tepid water. Simultaneously, 0.05 to 0.15 gm (50 to 150 mg) of emetine hydrochloride is administered hypodermically. These dosages are easily obtained from a 7.2 per cent solution of emetine supplemented by 1 per cent pilocarpine and 4.8 per cent ephedrine sulfate. Of this solution, 0.6 cc contains 50 mg of emetine, 1 cc contains 75 mg, and 2 cc 150 mg of emetine — the highest single dosage I have ever administered. The percentages in this solution have been arrived at purely

empirically. Experiments with higher concentrated solutions have shown slower or less complete absorption. In other words, 50 mg of emetine in a 13 per cent solution produced a slower and less powerful reaction than the same amount in a 7.2 per cent solution. On the other hand, solutions of less concentration than 7.2 per cent appeared too bulky and therefore uncomfortable.

Immediately prior to the expected emesis the patient is exposed to the sight, smell and taste of the alcoholic beverages that he preferred when on a spell of drinking. The drinks are offered in undiluted form ("straight") and in the usual dilutions ("highballs").

These sessions last twenty to thirty minutes and are repeated daily* for five or six days. They are followed by six or seven preventive one-day treatments, so-called reinforcements, given at intervals ranging from four to twelve weeks. Thus, the application of the initial series together with the reinforcements takes approximately a year. Some patients, anxious to obtain the widest possible margin of safety, ask after the first year of treatment for further reinforcements. Such second-year-treatments have consisted of a series of four reinforcements given at three-month intervals.

I should like to stress the fact that it would be erroneous to assume that this detailed description of the technic enables one to apply it safely and efficiently without an adequate apprenticeship. The reasons for caution are indicated by the great range and variety of the patient's reaction to the conditioned and unconditioned stimuli, innumerable imponderables decisive for the success or failure of the treatment, and the very narrow margin between underdosage and overdosage.

The next article in this series will deal with the physiologic risks of the treatment, indications, contraindications, efficacy and psychotherapeutic aspects.

*Provided no toxic symptoms ensue. Otherwise the sessions were postponed for the necessary length of time. These toxic side effects will be discussed in a later article.

MEDICAL PROGRESS

RESUSCITATION*

SIDNEY C WIGGIN, M D,† PETER SAUNDERS, M D,‡ AND GEORGE A SMALL, M D§

BOSTON

CARDIORESPIRATORY ARREST

IN THE multitude of clinical and experimental material reported in the last two decades, cardiac arrest and respiratory arrest are usually regarded as two distinct entities. It is true that certain events result in cardiac arrest, whereas other circumstances lead to cessation of respiration, however, because these two are so closely related in pathological physiology and in therapy, thinking on the problems engendered must, in every instance, include both. Synonymous with Courville's¹ phraseology, "respiro-cardiac crises," the term cardiorespiratory arrest is suggested as most appropriate and is used below in referring to this phenomenon.

Cardiorespiratory arrest is one of the most catastrophic events that may occur in medicine and presents the greatest possible emergency. It is characterized by the absence of the two vital functions, circulation and respiration, the patient is apparently dead.

Cardiorespiratory arrest often occurs as an operating-room accident because circumstances of anesthesia and surgery predispose to its development. Of the operating-room accidents in which the arrest occurs as a terminal event in a mortal disease² — for example, in coronary occlusion incidental to an operation, late intestinal obstruction or overwhelming sepsis — this condition may be considered irreversible, and little benefit may be expected from resuscitation. On the other hand, when cardiorespiratory arrest occurs accidentally as a result of factors such as anoxia, drug effect, idiosyncrasy to drugs and abnormal reflex action, there is a

period following the onset of the arrest during which the condition is reversible. Hence, if effective resuscitation is promptly instituted recovery will follow.

The wealth of clinical observation emanating from the operating room in the nature of case reports and discussions, in addition to the knowledge gained from experimental investigations, enables one to form a clearer concept of the problems involved and to place the treatment of this condition — namely, resuscitation, the revival of the apparently dead — on sound physiologic principles.

Cardiorespiratory accidents do not confine themselves to the operating room. In the delivery room, asphyxia of the newborn requires prompt resuscitation therapy, in the home, in industry and elsewhere accidents such as electric shock, drowning, inhalation of foreign material, inhalation of noxious gases, injuries to the chest and poisonings present emergencies in which a knowledge of resuscitation may make the difference between life and death. Therefore, the discussion that follows deals first with this emergency in the operating room, secondly, with the emergency in the delivery room and, finally, with accidents occurring elsewhere.

Pathological Physiology

Anoxia produced by cardiorespiratory arrest. A state of oxygen deficiency occurring in the tissues from whatever cause is designated as hypoxia; continuation of hypoxia to a state of oxygen lack incompatible with life is called anoxia. In the literature, the term anoxia is generally used to designate both hypoxia and anoxia, in the ensuing discussion, this usage of the word is followed.

Many clinical conditions lead to various degrees of anoxia. The most frequent cause is decrease in oxygen supply when oxygen demand is normal.³ Examples are as follows: insufficient oxygen in the atmospheric air (environmental cause) such as high altitude, insufficient intake of oxygen to the al-

§Resident in anesthesiology, Boston City Hospital.

veoli of the lungs (respiratory cause) such as respiratory arrest, respiratory depression, respiratory obstruction, emphysema, asthma, pneumonia, atelectasis and pulmonary fibrosis, inadequate transportation of oxygen from the alveoli of the lungs to the tissues (circulatory cause) such as cardiac arrest, failing circulation, myocardial weakness, valvular disease, pericarditis, arterial spasm and arteriovenous fistula, and depressed tissue activity such as frostbite and edema.

Less frequent causes of anoxia are associated with a normal oxygen supply, but an increased oxygen demand of the tissues (over-utilization anoxia)⁴—for example, exercise, fever, hyperthyroidism and infection. Whereas, the anoxia that develops with the above conditions may be gradual in onset and may be compatible with life for a long time, the anoxia that follows the complete cessation of respiration and circulation in cardiorespiratory arrest is rapidly destructive^{1, 5, 6} to certain vital tissues, especially the brain,⁷ and leads to death in a very short time.

In the human being complete cerebral anoxia for ten seconds produces unconsciousness, that for twenty to thirty seconds causes cessation of electroencephalographic brain waves, and that for three to five minutes produces irreversible pathologic change in the cerebrum.⁵ The medulla with its centers can survive for twenty-five to thirty-five minutes, and the spinal centers from forty to sixty minutes.⁸ The resistance of the brain in very young animals to circulatory arrest is much greater than that of the adult brain.⁹ This may well be the reason why resuscitative efforts have been rewarded with success, most often in young people. Courville's monograph discloses in detail the effect of anoxia on the nervous system, particularly the brain. He found alterations in the cerebral cortex characterized by degeneration of individual cells, patchy areas of necrosis, diffuse zonal necrosis and complete cortical disintegration. Microscopic alterations in the nerve cells explained the ultimate pathological picture encountered, these were sclerotic changes, acute degeneration, ischemic alteration, pigmentary atrophy and ferrugination of nerve cells. More recently, similar studies of post-mortem material have substantially corroborated Courville's findings.^{7, 10} Particularly striking are the degeneration of cerebral and basal-cell ganglions, disappearance of pyramidal cells of the cerebral cortex, increase in astrocytes, proliferation of microglia and severe destruction of the occipital cortex and superior temporal gyrus.

Demonstrable pathological findings caused by anoxia in organs other than the brain are relatively meager. Damage to the myocardium by anoxia⁵ is important because, although it develops less rapidly than that to the brain, it is responsible for the inability of the heart to recover from cardiorespiratory

arrest in cases in which cardiac resuscitation is unsuccessful. Of all tissues, the brain is the most vulnerable and susceptible to oxygen lack.^{1, 5, 6} This explains why in cases in which anoxia has advanced to the point where irreversible changes to the brain have occurred, although life is spared, permanent damage may follow. This can be the case in cardiorespiratory arrest when resuscitation saves life but is not effective enough to prevent permanent brain damage. The patient with permanent brain damage may be a vegetative organism¹¹ who lives on, a burden to himself and to society. In fatal cases, before death supervenes, there may be a period of coma lasting a few hours to many days.^{7, 12} When life is spared beyond this time, various neurologic changes will exist.¹³ Some of these will be permanent, and others will clear up completely.¹⁴ Blindness, deafness, Parkinsonian syndrome, athetoid and choreiform movements, speech defects and emotional instability are some of the sequelae in these cases.¹

This leads to the conclusion that the outstanding pathological result of cardiorespiratory arrest is the damage to the brain produced by anoxia.

Pathology leading to cardiorespiratory arrest

Cardiorespiratory arrest can occur when respiration and circulation fail simultaneously. Frequently, however, either respiration or circulation fails first, and the failure of the other function follows. Which of these functions fails first is immaterial,¹⁵ for each is dependent upon the other. When respiration ceases, from whatever cause, the progressive oxygen deficiency that follows depresses the mechanism of circulation until in a few minutes circulation ceases. Conversely, any condition that results in failure of circulation⁵ will very soon produce failure of respiration from anoxia. Experiments on cats in which the pulmonary artery was ligated showed that in thirty seconds blood pressure was unobtainable and in forty seconds breathing ceased, when the occlusion was relieved in less than three minutes, the animals recovered, after three minutes resuscitation was necessary, after four minutes, even with successful resuscitation, there were permanent neurologic changes.¹⁶ By oxygenation of the blood extracorporeally, survival times were notably prolonged. It has been demonstrated that the human brain is not so capable as that of the dog of withstanding suspension of circulation and returning to normal.¹⁷

Respiratory arrest The frequent causes of respiratory arrest are as follows: paralysis of the respiratory musculature—for example, that which occurs in excessive curarization¹⁸ or in spinal anesthesia when the anesthetic level reaches the upper cervical segments^{19, 20}, paralysis of the respiratory center which may be produced by various drugs such as anesthetics,^{5, 21} hypnotics and analgesics or by reflex effect such as that occurring during anesthesia when

a gross stimulus and insufficient depth of general anesthesia are present²² (another important factor in the production of central respiratory paralysis is the anoxia that develops from respiratory obstruction⁵)

In contrast to the above types of respiratory arrest, there is a condition in which cessation of spontaneous respiration occurs without any danger to the patient. In this case, the anesthesiologist deliberately produces respiratory arrest by the "apneic technic" in which he takes over the function of pulmonary ventilation from the patient.²³ This procedure, which is readily reversible, is based on the physiologic phenomenon of eliminating carbon dioxide excessively and thus depriving the respiratory center of its physiologic stimulus. At the same time, oxygenation is not interrupted. This technic is a common practice in anesthesia.

Cardiac arrest. Circulatory failure may be of two fundamental types: cardiovascular collapse typified by shock (a discussion of this subject has been deemed beyond the scope of this review), and cardiac arrest in which the causative factors have acted upon the heart or upon autonomic centers that control heart action and have resulted in the disqualification of the heart as the motive force in circulation.

In such an event as cardiac arrest, there are two possibilities: the ventricles are fibrillating, or the heart is at a standstill. Ventricular fibrillation has been described by Guedel²⁴ as "a wormlike movement of the ventricular muscle with the heart in full diastole. It consists of an unsynchronized contraction and relaxation of the individual muscle fibres which provide no circulation of blood." Thompson et al.²⁵ described ventricular fibrillation as an "electrodynamic dissolution of the cardiac cycle."

Development of ventricular fibrillation in dogs after occlusion of the circumflex branch of the left coronary artery is characterized by the occurrence of isolated extrasystoles, this is followed by long runs of ventricular extrasystoles, and then by irregular ventricular complexes that become increasingly rapid and finally are converted to ventricular fibrillation.²⁶ In the operating room the common cardiac dysrhythmias observed are ventricular and auricular extrasystoles, tachycardia, foci of ectopic beats and shifting pacemaker, any one of which may be the precursor of ventricular fibrillation.²⁷ It has been noted that manipulations of the heart producing changes in its position or stimulation to the epicardium are prone to result in cardiac arrhythmias and that when ventricular extrasystoles or ventricular tachycardia occurs very often ventricular fibrillation follows.^{28, 29} Factors of etiologic significance in ventricular fibrillation¹⁰ include agents that sensitize the heart by their own action such as cyclopropane, chloroform and ethyl

chloride³⁰, hypoxia, which increases myocardial irritability and also causes an increase in epinephrine output³¹, emotional states such as fear by virtue of stimulating an outpouring of epinephrine³², and excessive vagal stimulation.³²

Danielopolu and Marcou³³ pointed out that in dog and cat experiments, ventricular fibrillation is often produced by asphyxia, chloroform and manipulation of abdominal viscera. Other demonstrations have proved that ischemia of the myocardium of the dog markedly reduces the fibrillation threshold of the heart to artificial stimuli.³⁴ Harken and Norman²⁷ classify the factors that can be responsible for cardiac arrhythmias as follows: reflex mechanisms,³⁴ which are related to the position of the patient during operation, intratracheal, intrabronchial and intrapulmonic stimulation, chest-wall manipulation and sudden alterations in blood volume, chemical changes in the blood stream, particularly, hypoxia and toxicity or sensitivity to drugs, and direct cardiac and intracardiac manipulation producing pericardial, epicardial or myocardial stimulation, and dislocation of the heart from its position of optimum function.²⁸

Stutzman and his co-workers³⁰ observed that ventricular fibrillation occurring under cyclopropane anesthesia is dependent upon a reflex. This reflex has its receptors in the abdominal viscera, particularly in the mesentery from which autonomic afferent pathways travel to a brain center above the pons, from there, efferent pathways lead by way of the sympathetic nervous system to the heart.

Little has appeared in the literature regarding the pathology of the condition termed cardiac standstill as compared to ventricular fibrillation. This state, which is characterized by the complete absence of activity of the myocardium,³² "the asystolic heart,"³⁵ may develop suddenly owing to an overwhelming vagal reflex³ or may develop gradually in relation to hypoxia when progressive weakening of contractions occurs. When the state of standstill is reached, the heart is in some degree of dilatation, and the irritability of the myocardium is relatively low. If the irritability of such a heart is increased, at some point the myocardium may start to fibrillate.³⁶ The presence of anoxia may support the change from cardiac standstill to ventricular fibrillation. For practical purposes, the heart that is not asystolic but has feeble, ineffective contractions can be considered in the same category as the heart in standstill.

Pharmacologic Action of Drugs on the Brain and Heart in Cardiorespiratory Arrest

The susceptibility or resistance of the brain to anoxia depends largely on the state of its cellular activity. The highly active brain having a high oxygen demand will suffer more from oxygen lack, whereas the brain whose function is depressed can resist anoxia to some extent.³⁷ Drugs that stimulate

the central nervous system will increase its oxygen demand, thus, in cardiorespiratory arrest such drugs will aggravate the danger of damage from anoxia³⁸ For this reason, analeptic and sympathomimetic drugs, such as caffeine, coramine, metrazol, strychnine, ephedrine, Benzedrine, Neo-Synephrine and paredrine, which formerly were called upon in cardiorespiratory emergencies, are condemned⁵ Conversely, drugs such as anesthetics and analgesics³⁸ that depress the central nervous system and thereby decrease its oxygen demand may be responsible for prolonging the survival time of the brain cells during periods of anoxia^{14 39}

Epinephrine stimulates the heart by a direct effect on the myocardium and on the conduction tissue^{40 41}, it produces more forceful contractions of the myocardium³⁶ Objections raised against the use of epinephrine in cardiorespiratory arrest are based upon its ability to increase myocardial irritability,^{14 30 42-44} to elevate markedly the oxygen consumption of the heart muscle⁴⁵ and to increase the speed of auriculoventricular conduction time Because of these properties, when epinephrine is administered in the presence of a failing heart in which a state of cardiac standstill or a prefibrillation arrhythmia exists, it may produce ventricular fibrillation When the drug is used, Hyman³⁵ and Mautz⁴⁵ recommend that it be injected into the heart muscle, where it is most effective, Harken and Norman²⁷ recommend that it be injected into the right ventricle, whereas Dripps et al¹⁴ choose injection into the auricle, where it is least likely to cause ventricular fibrillation

Procaine hydrochloride diminishes the irritability of the conduction system of the heart and of the myocardium, thereby causing reversion of prefibrillation dysrhythmias to normal rhythm⁴⁶ Hence it has a definite *protecting effect* on the heart against ventricular fibrillation^{42 43 45 47 48} On the other hand, although admitting that procaine raises the fibrillation threshold of the ventricles, Wiggers and Wegria⁴⁹ and Fauteux⁵⁰ believe that procaine does not prevent ventricular fibrillation This contention is supported by a case reported by Harken and Norman²⁷ in which ventricular fibrillation occurred after the patient had been "procainized"

The role of procaine in *defibrillation*—that is, reversal of ventricular fibrillation—of the heart is questionable Stutzman et al⁵¹ failed to control ventricular fibrillation induced by cyclopropane-epinephrine with the intravenous injection of procaine Harken and Zoll⁵² corroborated these experiences On the other hand, a number of reports demonstrate the successful use of procaine in defibrillation of the heart^{13 26 44 45 48 53} Procaine is recommended for intravenous administration in 1 per cent solution⁴⁵, doses are 40 to 100 mg in single injections up to a maximum of 200 mg⁵⁴

Atropine and scopolamine by virtue of their blocking of vagal effects on the sinoauricular pace-

maker protect the heart to some extent against reflexes that may precipitate cardiorespiratory arrest^{25 55}

In addition to their main effect on the myocardium digitalis and strophanthin act upon the auriculoventricular conduction system to increase the refractory period and slow the rate of conduction⁵⁶ The latter action protects the heart to some extent in states of increased irritability Toxic effects from these drugs on the heart may result in arrhythmias of which ventricular tachycardia is the most serious, this may be the precursor of ventricular fibrillation⁵⁶

Quinidine acts upon the heart to decrease myocardial excitability and to slow conduction of impulses in the heart muscle thereby reducing the danger of ventricular fibrillation It has attained some favor as a preventive measure when it is given preoperatively in the presence of all cardiac arrhythmias with the exception of auricular fibrillation^{26 27 45 57}

Calcium chloride and barium chloride are cardiac stimulants that increase the force of myocardial contractions^{50 58}

Potassium relaxes the myocardium, it may produce cardiac inhibition and stop ventricular fibrillation^{56 58 59}

Effect of Electric Stimulation upon the Heart

When an electric current of sufficient strength is accidentally passed through the body it may cause ventricular fibrillation or cardiac standstill from inhibition of the conduction mechanism or paralysis of the myocardium^{6 59} Experimental work has demonstrated that it is possible to apply an electric current to the heart for therapeutic purposes Wiggers⁶⁰ introduced a method of treating ventricular fibrillation (the technic of "serial defibrillation") in which he applied a momentary shock 1.0 ampere in strength of a 60-cycle alternating current, through two electrodes, which were placed on opposite sides of the heart Three to seven shocks were required to stop fibrillation He reasoned that each shock resulted in the merging of small fibrillating areas into progressively larger ones until with the final shock all fibrillation was arrested At this moment cardiac standstill was produced and the problem of reinstituting rhythmic cardiac activity remained

Experiences of Hooker et al,⁶¹ Beck and his co-workers⁶² and Lampson and his associates⁴⁴ have confirmed the usefulness of this procedure in defibrillation of the heart The equipment required is relatively simple

Diagnosis of Cardiorespiratory Arrest

The diagnosis of respiratory arrest does not present any problem, for cessation of respiration can readily be observed But the recognition of cardiac arrest may be quite difficult⁴⁴ If the opera-

a gross stimulus and insufficient depth of general anesthesia are present²² (another important factor in the production of central respiratory paralysis is the anoxia that develops from respiratory obstruction⁵)

In contrast to the above types of respiratory arrest, there is a condition in which cessation of spontaneous respiration occurs without any danger to the patient. In this case, the anesthesiologist deliberately produces respiratory arrest by the "apneic technic" in which he takes over the function of pulmonary ventilation from the patient.²³ This procedure, which is readily reversible, is based on the physiologic phenomenon of eliminating carbon dioxide excessively and thus depriving the respiratory center of its physiologic stimulus. At the same time, oxygenation is not interrupted. This technic is a common practice in anesthesia.

Cardiac arrest. Circulatory failure may be of two fundamental types: cardiovascular collapse typified by shock (a discussion of this subject has been deemed beyond the scope of this review), and cardiac arrest in which the causative factors have acted upon the heart or upon autonomic centers that control heart action and have resulted in the disqualification of the heart as the motive force in circulation.

In such an event as cardiac arrest, there are two possibilities: the ventricles are fibrillating, or the heart is at a standstill. Ventricular fibrillation has been described by Guedel²⁴ as "a wormlike movement of the ventricular muscle with the heart in full diastole. It consists of an unsynchronized contraction and relaxation of the individual muscle fibres which provide no circulation of blood." Thompson et al.²⁵ described ventricular fibrillation as an "electrodynamical dissolution of the cardiac cycle."

Development of ventricular fibrillation in dogs after occlusion of the circumflex branch of the left coronary artery is characterized by the occurrence of isolated extrasystoles, this is followed by long runs of ventricular extrasystoles, and then by irregular ventricular complexes that become increasingly rapid and finally are converted to ventricular fibrillation.²⁶ In the operating room the common cardiac dysrhythmias observed are ventricular and auricular extrasystoles, tachycardia, foci of ectopic beats and shifting pacemaker, any one of which may be the precursor of ventricular fibrillation.²⁷ It has been noted that manipulations of the heart producing changes in its position or stimulation to the epicardium are prone to result in cardiac arrhythmias and that when ventricular extrasystoles or ventricular tachycardia occurs very often ventricular fibrillation follows.^{28, 29} Factors of etiologic significance in ventricular fibrillation¹⁰ include agents that sensitize the heart by their own action such as cyclopropane, chloroform and ethyl

chloride³⁰, hypoxia, which increases myocardial irritability and also causes an increase in epinephrine output³¹, emotional states such as fear by virtue of stimulating an outpouring of epinephrine³², and excessive vagal stimulation.³³

Danielopolu and Marcou³³ pointed out that in dog and cat experiments, ventricular fibrillation is often produced by asphyxia, chloroform and manipulation of abdominal viscera. Other demonstrations have proved that ischemia of the myocardium of the dog markedly reduces the fibrillation threshold of the heart to artificial stimuli.³¹ Harken and Norman²⁷ classify the factors that can be responsible for cardiac arrhythmias as follows: reflex mechanisms,³⁴ which are related to the position of the patient during operation, intratracheal, intrabronchial and intrapulmonic stimulation, chest-wall manipulation and sudden alterations in blood volume, chemical changes in the blood stream, particularly, hypoxia and toxicity or sensitivity to drugs, and direct cardiac and intracardiac manipulation producing pericardial, epicardial or myocardial stimulation, and dislocation of the heart from its position of optimum function.²⁸

Stutzman and his co-workers³⁵ observed that ventricular fibrillation occurring under cyclopropane anesthesia is dependent upon a reflex. This reflex has its receptors in the abdominal viscera, particularly in the mesentery from which autonomic afferent pathways travel to a brain center above the pons, from there, efferent pathways lead by way of the sympathetic nervous system to the heart.

Little has appeared in the literature regarding the pathology of the condition termed cardiac standstill as compared to ventricular fibrillation. This state, which is characterized by the complete absence of activity of the myocardium,³² "the asystolic heart,"³⁵ may develop suddenly owing to an overwhelming vagal reflex³² or may develop gradually in relation to hypoxia when progressive weakening of contractions occurs. When the state of standstill is reached, the heart is in some degree of dilatation, and the irritability of the myocardium is relatively low. If the irritability of such a heart is increased, at some point the myocardium may start to fibrillate.³⁶ The presence of anoxia may support the change from cardiac standstill to ventricular fibrillation. For practical purposes, the heart that is not asystolic but has feeble, ineffective contractions can be considered in the same category as the heart in standstill.

Pharmacologic Action of Drugs on the Brain and Heart in Cardiorespiratory Arrest

The susceptibility or resistance of the brain to anoxia depends largely on the state of its cellular activity. The highly active brain having a high oxygen demand will suffer more from oxygen lack, whereas the brain whose function is depressed can resist anoxia to some extent.³⁷ Drugs that stimulate

ecuted and the patient does not seem to have adequate excursions of the thorax the air passages are obstructed. It is then necessary to insert oral nasal or tracheal airways or to remove any foreign material that may be causing the obstruction.¹⁰ The interruption of the administration of oxygen while such manipulations take place must be for the briefest possible time. When an anesthesia machine is not available in the operating room, the same intermittent administration of oxygen may be accomplished by a simple arrangement consisting of a face mask, rubber rebreathing bag and cylinder of oxygen.²⁵ No operating room should function without an anesthesia machine or, at the very least, the latter equipment.

Mautz⁷¹ has described an attachment to the anesthesia machine that utilizes compressed air as the source of the force that ventilates the lungs. Kreiselman's⁷² resuscitator produces intermittent flow of oxygen under adjustable positive pressure. Other less simple apparatus that effect rhythmic inflation of the lungs followed by rhythmic suction—so-called "suck and blow" resuscitators—are recommended by Thompson et al.^{25, 73, 74} and Schwerma and his co-workers.⁷⁵

It has been pointed out that in addition to providing efficient pulmonary ventilation the application of alternating positive and negative pressure has beneficial effects on the circulation and initiates stimulatory impulses for respiration.^{73, 74, 76, 77} Disapproval of these resuscitators is based upon the possibility of damage to the lungs and the fact that unskilled application greatly reduces their usefulness and exposes the circulation to harmful effects.^{75, 79} Mousel, Stubbs and Kreiselman⁵ state that such apparatus should not be relied upon in these emergencies.

A recently introduced method of artificial respiration employs electric stimulation of the phrenic nerve thereby producing rhythmic contractions of the diaphragm, which will provide adequate pulmonary ventilation.⁸⁰⁻⁸² Practical considerations at present limit this promising method.

In cases where the anesthesia machine or the simple arrangement referred to above is not available in the operating room (the existence of such a deplorable situation must be condemned) methods of manual artificial respiration or mouth-to-mouth insufflation must be resorted to. Of the manual methods, the rib-retraction technic of Viswanathan⁸³ is regarded as superior to the method of Schafer⁸⁴ or Silvester.⁸⁵ These manual methods of artificial respiration are difficult and unsatisfactory.⁵

Artificial circulation For re-establishing circulation several approaches are described.

Employment of an extracorporeal pump as the source of motive power in the circulation has been mentioned but is not as yet available.^{16, 27, 48}

Another approach to the problem includes mechanical stimuli³⁵ such as needle puncture^{25, 87} of the heart, percussion²⁵ and compression¹⁵ of the chest wall, and incision or pinching³³ of the pericardium. Intracardiac injections of epinephrine, procaine or Neo-Synephrine,⁸⁸ or a combination of procaine and epinephrine,¹⁰ and intravenous injections of drugs such as ether, caffeine sodium thiosulfate, Ronzini's solution, camphor, digitalis, strophanthin, Metrazol, coramine strychnine, 20 per cent dextrose and hypertonic saline solution have all had their proponents.³⁵ Beneficial results following some of these measures are reported, however, uncertainty regarding indications for and outcome of this approach is obvious.

The third approach employs the heart as the pump of the circulation, but utilizes the force from the operator's hand rather than that of the myocardium. This method of manual compression (cardiac massage) requires adequate exposure of the heart. The direct approach through the chest wall by a transverse incision in the fourth left intercostal space, with division of the fourth and fifth costal cartilages, is believed to be superior to an abdominal incision with an attempt to reach the heart through either an intact or an incised diaphragm.^{2, 14, 64, 89} The heart is grasped and compressed firmly at the rate of twenty to forty times a minute, depending upon the adequacy with which the ventricles fill between compressions.^{14, 27} With effective cardiac massage, the radial pulse often can be felt and the blood pressure may be as much as 60 or 70.¹⁴ To increase blood flow through the coronary arteries and the brain, the clamping of the aorta distal to the left carotid artery may be helpful.²⁷ Cardiac massage is the most efficient method of providing for artificial circulation and is first choice in the technic of cardiac resuscitation.^{2, 14, 27, 64, 89}

Why this is not fully appreciated is probably due to the general lack of familiarity with the technic. It is hoped that this relatively simple, life-saving surgical procedure will be included among the fundamental essentials in undergraduate and postgraduate surgical training.^{15, 90}

A prearranged plan for meeting the emergency of cardiorespiratory arrest with a specific assignment for each member of the operating-room team is recommended.^{64, 90}

When the first goal of resuscitation—that of oxygenation of the tissues by the administration of artificial respiration (for which the anesthesiologist with his machine is best suited)—with the simultaneous production of artificial circulation by cardiac massage (which is best performed by the surgeon²⁹) has been attained the second aim of resuscitation may be pursued without confusion and haste.

tive wound does not permit the inspection or palpation of the heart or a major artery, there is little reliable guide for positive diagnosis. The situation that may occur at this time is aptly described by Dripps and his colleagues¹⁴: "The majority of patients are doomed because minutes which cannot be spared are wasted in searching for a stethoscope, in frantic palpation of a succession of arteries, in hasty consultation with colleagues summoned to judge a situation with which they are unfamiliar."

Various diagnostic procedures such as visualization of pulsations of the retinal vessels through an ophthalmoscope,¹⁴ inhalation of amyl nitrite to stimulate forceful contractions in a feebly beating heart,⁶⁵ observation of the speed of capillary refill¹⁴ and examination of an electrocardiographic tracing⁶⁵ are either unreliable or impractical.¹⁴ Therefore, in the words of Dripps and his co-workers:

Opening the thorax is the only conclusive diagnostic procedure. If the heart has stopped or the ventricles are fibrillating, minutes can be saved by adopting the attitude of rapidly opening the chest for diagnosis, whereas if the heart is beating feebly, little harm may have been done.

In cardiorespiratory arrest the clinical judgment of the anesthesiologist, who has closely observed the patient during the preceding period and who is aware of the internal and external factors that may have affected the patient's physiology, plays an important role in the evaluation of this emergency.

Prophylaxis

Undoubtedly the most important factors in the prophylaxis of cardiorespiratory arrest lie in the anesthetic management of the patient. Mousel and his associates⁵ state that the intelligent and judicious handling of the patient in the preoperative period and during anesthesia will prevent most of the harmful sequelae.⁴⁰

In the preoperative period, protective measures calculated to diminish the incidence of cardiorespiratory accidents are as follows: regulation of fluid and electrolyte balance, restriction of water and sodium intake in elderly patients and those having poor cardiorenal reserves, the proper use of digitalis and quimidine in selected cases, and the careful choice of premedicating agents that allay excitement and irritability, reduce oxygen need and inhibit parasympathetic functions.²⁷

The most important preventive measure during anesthesia is the maintenance of adequate oxygenation at all times. Ruth,⁶⁶ in his studies of anesthetic accidents, found that the most common error during the period preceding the accident was that the anesthetist tolerated anoxia in his patient.

Of similar importance is the proper selection of anesthetic agents and their skillful administration. A specific preventive measure is intravenous in-

jection of procaine or procaine applied topically to the pericardium during thoracic operations.²⁷ To protect the patient from ventricular fibrillation that may occur under cyclopropane anesthesia, the addition of ether to the inhaled gases is recommended. On the basis of the findings of Stutzman et al.³⁰ it seems likely that a spinal anesthetic administered prior to cyclopropane anesthesia has a similar protecting effect.

Finally, and by no means any less in importance, is the close co-operation between the surgeon and anesthetist that is necessary in minimizing manipulations, especially during light anesthesia, which may initiate dangerous reflexes.²⁸

Treatment of Cardiorespiratory Arrest

Two aims are apparent in the treatment of cardiorespiratory arrest.

The first and immediate goal is to deliver oxygen to the tissues. Whether or not life is saved, or, if life is spared, whether or not permanent brain damage is suffered, is dependent upon the early and successful accomplishment of the foregoing principle.^{1, 10, 61} The first aim is attained by simultaneously providing ventilation of the lungs by artificial respiration and artificial circulation by cardiac massage. By these procedures, oxygen is taken into the alveoli of the lungs, from which it is transported by the blood and delivered to all the body tissues. When this is accomplished, the greatest immediate danger — namely, that the cardiorespiratory arrest will become irreversible — is passed.

Artificial respiration. The fundamental principles that must be observed in artificial respiration are as follows:⁶³ intermittent rhythmic exchange of atmosphere in the patient's lungs must be started at the rate of sixteen to twenty times a minute, any obstruction of the throat and air passages must be relieved as quickly as possible, and adequate time must be allowed for the lungs to empty after each inflation.

Since the production of the highest possible concentration of oxygen in the alveoli of the lungs is desired, 100 per cent oxygen should be used.^{10, 63} The opinion is commonly held that carbon dioxide should not be added to oxygen for resuscitative purposes because the patient whose respiration has ceased is unable to eliminate carbon dioxide retained in his blood and tissues.^{5, 63} If artificial sources of oxygen are not available, atmospheric air or even the exhaled air of the operator may be used.

In the operating room, where cardiorespiratory arrest is most likely to occur, artificial respiration is best accomplished by rhythmic compression, with the force equivalent to about 20 mm of mercury, on the breathing bag of the anesthesia machine.^{69, 70} This must be promptly instituted after spontaneous respiration has ceased. If this intermittent administration of oxygen is properly ex-

The second aim is to re-establish the vital functions — spontaneous heart action and respiration — and to attain complete recovery of the patient

The recommended treatment when the heart has been found in ventricular fibrillation is serial defibrillation and the intravenous administration of procaine^{15 42 43 62}. Intracardiac injection of 10 cc of 1 per cent potassium chloride may be helpful in defibrillating the heart^{55 59}. After defibrillation, the situation is identical with that of cardiac standstill, and effective cardiac massage is the most important measure until spontaneous rhythmic contractions are resumed^{14 27 29}. When contractions start, they may be quite feeble. At this time, the administration of 0.5 cc of a 1:1000 solution of epinephrine into the right ventricle^{14 27} or auricle will help strengthen the heart beat. This is perhaps the only place for administration of epinephrine in cardiac resuscitation^{27 29 44}. The injection of 1 or 2 cc of 0.5 per cent solution of barium chloride^{36 50 51} or 10 cc of 1 per cent solution of calcium chloride^{20 45} into the heart serves the same purpose.

Resumption of spontaneous respiration does not require any specific measures. If proper oxygenation of the brain has been maintained, respiration will be re-established when the respiratory center recovers from the depression incident to cardiorespiratory arrest.

In order to further the attainment of complete recovery, adjunctive therapy is desirable: continuation of inhalation therapy through a free airway and attention to maintaining an adequate urinary output by supplying sufficient fluids and electrolytes are indicated. Prophylactic measures for the prevention of pulmonary infection, hypostatic congestion and distention of the bladder are necessary.¹⁴

Prognosis

Dripps and his associates¹⁴ state that, in general, if prompt diagnosis is followed by prompt therapy, the heart beat can be restarted. This thesis is supported by the studies of Kountz,⁹¹ who examined the hearts of persons a short time after death and demonstrated that the heart is an amazingly resistant organ possessing rhythmicity and contractility that are difficult to destroy.

Factors such as the time element in instituting effective therapy, the age of the patient and the cardiac status prior to the catastrophe will ultimately determine whether the heart can be restored to normal function.¹⁴ The anoxia that develops because of delay in diagnosis and in establishing effective artificial respiration and cardiac massage may so damage the myocardium that it resists all efforts at resuscitation. The myocardium damaged by pre-existing toxemia, arteriosclerosis, hypertension, coronary insufficiency or narcosis is much less likely to recover.¹⁴ Wiggers⁴⁹ found that failure to recover from ventricular fibrillation de-

pended not so much on the inability to defibrillate the heart as on the subsequent inability of the myocardium to resume vigorous beating.^{50 62}

If the heart returns to regular rhythm and blood pressure is maintained, what will be the status of the central nervous system? The prognosis is determined by the duration of cerebral anoxia.¹⁴ Clinical experiences as well as the work of Weinberger, Gibbon and Gibbon⁹² indicate that if the cardiorespiratory arrest has not exceeded two to four minutes, complete recovery may be expected. This is well illustrated by more than 70 cases reported with complete recovery.^{2 10 12 14 22 44 53 67 64 89 90}

Spontaneous respiratory activity may be expected to reappear within five to thirty minutes once cardiac activity has been resumed. If cardiorespiratory arrest has been slightly more prolonged, convalescence may be stormy but may show progressive improvement with each passing hour.¹⁴ This period is characterized by acute febrile responses, muscular rigidity, twitching, convulsions, hyperflexia and varying degrees of coma.^{1 14} The time of onset and the duration of these phenomena are prognostically significant. The persistence of coma beyond the first twelve hours is an unfavorable finding. In this case, consciousness is not likely to return, and the heart may again cease to beat within a few minutes to several weeks. If consciousness is regained, partial recovery — that in which residual neurologic symptoms persist — or complete recovery may follow.¹¹

* * *

Commenting on the problem of cardiac resuscitation, Dripps and his colleagues¹⁴ emphasize the necessity for greater awareness on the part of the anesthesiologist and surgeon of the implications of this accident. They also raise the question of approaching the problem from other points of view. What are the possibilities of protecting the brain from anoxia by preoperative measures, and what are the roles of intra-arterial and intracardiac infusions? Of what value will the oxyhemograph be in diagnosis of anoxia and prevention of cardiorespiratory arrest?^{742 92 96}

These seem to be problems for the future. The greatest problem of the present is pointed out by Mousel, Kreiselman and Stubbs who emphasize the fact that the conduction of an anesthesia expressly designed to prevent complications is of the utmost importance. They claim that the incidence of fatal accidents is more than twenty times greater in institutions where the type of anesthetic organization is poor or even average as compared to that in institutions where the best in anesthesia is available. This is understandable since the special knowledge and skill of the anesthesiologist may nowhere be more valuable than in the prevention diagnosis and treatment of cardiorespiratory arrest.

(To be concluded)

dice, spider-type telangiectasia on the skin, a Grade II pulmonic systolic murmur, bilateral basal inspiratory rales and a tender firm liver edge, palpable three fingerbreadths below the costal margin.

The blood pressure was 120 systolic, 80 diastolic. The temperature was 100°F by rectum, the pulse 90, and the respirations 18.

Examination of the blood showed a white-cell count of 4000, with 51 per cent neutrophils, 40 per cent lymphocytes, 8 per cent monocytes, and 1 per cent eosinophils. The urine specific gravity was 1.015, with a +++ test for bile, and the sediment was normal. The stools were guaiac negative and bile positive. The serum alkaline phosphatase was 9.6 units per 100 cc, the prothrombin time 28 seconds (control, 15 seconds), and the cholesterol 161 mg, and the cholesterol esters 44 mg per 100 cc, the serum albumin was 2.6 gm per 100 cc, and a globulin of 3.7 gm. The nonprotein nitrogen was 24 mg per 100 cc, and the van den Bergh reaction 11.2 mg per 100 cc direct, 17.4 mg indirect. The cephalin flocculation was +++ in twenty-four hours, the thymol turbidity ++, and the urinary urobilinogen 6.5 Ehrlich units.

A gastrointestinal series demonstrated esophageal varices. The spleen was enlarged. There was no evidence of opaque calculi in the region of the gall bladder.

In the hospital the patient's appetite was poor, and dependent edema and ascites appeared. Therapy included mercurial diuretics, intravenous injection of albumin, a high-calorie, high-carbohydrate and high-protein diet and vitamin K. Oliguria appeared and was persistent. Drowsiness and stupor followed. In the last two weeks in the hospital the temperature was irregularly elevated.

The temperature reached 104 to 105°F, where it persisted for two days, when she died, one month after admission.

DIFFERENTIAL DIAGNOSIS

DR ALFRED E. KRANES: There are a number of interesting features about this problem. When I first read it, I was very much impressed by the apparent and striking discrepancy between the history and the laboratory findings. To me, the history was suggestive of disease of the extrahepatic biliary ducts, and if the pain could in any way be fitted into the terminal illness, it seemed reasonable to ascribe it to intermittent obstruction of the biliary ducts. And yet, when we come to the terminal illness, one is struck by the fact that all the laboratory findings given here point almost unequivocally to intrahepatic disease. Certainly, the presence of bile in the stools, the positive cephalin-flocculation test, the cholesterol finding and the marked urobilinogenuria point, without much question, to intrinsic disease of the liver. I have always believed that when the laboratory

findings and the history are at variance, it is always better to disregard the laboratory findings and rely on the history if it is a good one. However, I do not see how it is possible to disregard the impressive array of evidence for intrahepatic disease in this case. Furthermore, we have x-ray evidence of esophageal varices, which always mean to me diffuse fibrosis of the liver. May we see these films now?

DR STANLEY M. WYMAN: The varices are well demonstrated in the lower esophagus, there being apparently several quite large, tortuous vessels. The spleen is at the upper limits of normal, if not definitely enlarged. There seems to be a compression of the superior lateral aspect of the duodenal cap, possibly from the liver or from the gall bladder. There may even be some tortuosity of the folds of the stomach over and above what one expects, to raise the question of varices in the stomach.

DR KRANES: I wonder if anyone has any idea how long it would take for varices to appear? Let us put it this way. In how short a time may varices appear?

DR TRACY B. MALLORY: In a well documented case of post-necrotic cirrhosis following hepatitis that Wallgren¹ reported, the patient, a young boy, died of ruptured esophageal varices eight months after acute hepatitis.

DR KRANES: You certainly would not expect it to occur before several years in the usual case, would you?

DR MALLORY: I think it could occur in a period as short as two or three years.

DR MYLES P. BAKER: Dr Schatzki told me that four years was about the shortest time.

DR KRANES: It is a difficult determination to make, but it is of interest in this case.

To go back to the history for a moment, what interested me very much was how the patient with this history was able to escape more in the way of surgery or diagnostic studies over a period of twenty years. Because this history of twenty years is being compressed into a very short space, it may be that some relevant information was left out.

DR MALLORY: I have seen doctors and nurses do just that, Dr Kranes.

DR KRANES: Yes, and this patient was a nurse. She may have been an extremely stoical person and may not have consulted anyone.

It does surprise me that during twenty years no Graham test was done, and no other studies carried out. I am also intrigued by the innocent sounding statement, "When an appendectomy was performed several years before admission an infantile uterus was found." I must confess that I am more interested in what the gall bladder looked like at that operation, than in how the uterus appeared. Again, we have no information at all about that. Do we know whether the incision was made in the lower abdomen? I wonder why the operation was

CASE 35361

PRESENTATION OF CASE

A thirty-nine-year-old practical nurse was admitted to the hospital complaining of jaundice.

Twenty years before admission she had an attack of "acute indigestion." Her physician diagnosed a gall-bladder attack, but it subsided overnight and no operation was performed. In the subsequent two decades she had repeated attacks of similar pain. It was characterized by epigastric discomfort, "as if you had a stone and tried to push it through something and it won't go," and sometimes by an ache, radiating occasionally to both sides of the upper abdomen, to the right back and to the shoulder. The duration of the pain varied from thirty minutes to five hours. It was often more severe at night, and sometimes awakened the patient from sleep. The onset of pain

was sudden. Nausea was sometimes present during attacks. There was no vomiting. The attacks occurred about once monthly, but had increased in frequency in the past several years. She went on a fat-free diet at one time without relief. Ten months before admission, she had slight malaise, "dry eyes" and a temperature of 103°F. On the following day she felt well. This phenomenon occurred every two to four weeks. There were no chills or associated abdominal pain. Eight months before admission she noted easy fatigability and weakness. One month before admission mild itching appeared at night, but it subsided in the past two weeks. Three weeks before admission jaundice, dark urine and fever appeared, and persisted. The temperature sometimes reached 103°F. There was no change in the color of the stools. She had received no blood transfusions and had had no recent exposure to others with jaundice. There was no alcoholic consumption, her appetite remained good, and food intake was unrelated to pain.

One week before admission she entered a community hospital, where the following were noted: jaundice, extreme right-upper-quadrant tenderness and a palpable and slightly tender liver edge. The serum albumin was 4.0 gm per 100 cc, with a globulin of 2.8 gm, the prothrombin time 47 seconds (normal, 16 seconds), the blood Hinton reaction negative, the icteric index 57 per cent, the bleeding time 1½ minutes and the clotting time 5½ minutes.

The patient had never menstruated. When an appendectomy was performed several years before admission an infantile uterus was found. There had been occasional swelling around the ankles on prolonged standing.

When she was transferred to this hospital for further study physical examination showed jaun-

DR KRANES That is an interesting point and one that I should have brought out in the discussion. During the course of the ordinary portal cirrhosis, one occasionally sees patients with severe attacks of upper abdominal pain — and sometimes right-upper-quadrant pain — mimicking biliary colic in many respects, and at autopsy there appears to be no morphologic explanation.

CLINICAL DIAGNOSES

Cholemia
Liver disease of unknown nature

DR KRANES'S DIAGNOSIS

Cirrhosis of liver, biliary type

ANATOMICAL DIAGNOSES

Portal cirrhosis of liver, postnecrotic type
Splenomegaly

PATHOLOGICAL DISCUSSION

DR MALLORY The one diagnostic measure that today is usually applied to a cirrhotic patient is that of an aspiration biopsy from the liver. In this case, it was never thought safe to do it because the prothrombin time could not be brought down to normal.

The autopsy was, unfortunately, limited to examination of the peritoneal cavity so that I cannot give complete findings. However, the liver, which had been reported as three or four fingerbreadths below the costal margin, weighed only 750 gm — barely half normal. It was shrunken diffusely fibrotic coarsely nodular and rather characteristic of the postnecrotic type of portal cirrhosis. The gall bladder and extrahepatic ducts were normal, with no stones and no evidence of cholangitis. Either post mortem or in the agonal period a gas-bacillus infection had developed, and there were a great many gas bubbles throughout the liver, making the histology rather poor. But still, I think, we can safely eliminate cholangitis and feel sure that it was a postnecrotic type of cirrhosis. I believe the multiple attacks of pain were of the type that one sees in portal cirrhosis that can mimic gall-bladder colic in a fashion that often leads to exploration and nothing is found to explain it.

DR BAKER Do you think this started originally with acute viral hepatitis without any necrosis and went to the point of cirrhosis?

DR MALLORY It could have been. It would be indistinguishable from the type that we see in patients following arsenical or cinchophen therapy and so forth.

DR KRANES One would have to assume that these attacks of upper abdominal pain due to portal cirrhosis had been present for twenty years.

DR MALLORY I think that is possible. It was an old, inactive process. The spleen was estimated as weighing 900 gm — markedly enlarged.

DR KRANES How about the attacks of fever? They are not very well explained.

DR MALLORY There is no adequate explanation. But, as I say, we did not have a complete autopsy. We might have found something in another part of the body to account for it. I do not believe that this gas-bacillus infection could have existed for more than a few hours before death.

CASE 35362

PRESENTATION OF CASE

A fifty-one-year-old painter was admitted to the hospital because of vomiting and gnawing epigastric pain.

The present illness dated back some twenty-five years before, when he first noticed the onset of gnawing epigastric pain, occasional vomiting and "indigestion" relieved by sodium bicarbonate. X-ray examination at that time revealed a peptic ulcer. On therapy, consisting largely of diet, the patient became asymptomatic rather rapidly. One year later he discontinued his diet and since that time had intermittent recurrence of mild to moderate distress. Two years before admission he noticed the onset of occasional vomiting. Following a gastrointestinal series taken a few months later he was told that there was some obstruction at the site of the old ulcer. During the two months before entry to the hospital he had increasing difficulty retaining food and vomited frequently. He lost about 16 pounds of weight during this period. At no time had there been hematemesis or melena. A review of the systems revealed that the patient had had frequency and mild burning on urination during the recurrences of the gastrointestinal symptoms. He had nocturia every two hours during the two-month episode that brought him to the hospital. He had noted no hematuria, chills, fever or costovertebral-angle tenderness.

Physical examination revealed a well nourished, well developed man in no apparent distress. The chest was clear, the heart was normal. The abdomen showed only hyperperistalsis.

The temperature, pulse and respirations were normal. The blood pressure was 120 systolic, 80 diastolic.

Examination of the blood disclosed a nonprotein nitrogen of 39 mg and a total protein of 6.6 gm per 100 cc. The blood chloride was 98 milliequivalents per liter. The phenolsulfonphthalein test showed 33 per cent excretion of the dye in two hours. The blood hemoglobin was 12.9 gm. The white-cell

done — I suppose for the attacks of pain that she had

DR MALLORY It was a midline lower abdominal incision — 18 cm long, however

DR KRANES I was about to say that the surgeons may have operated expecting to find disease of the gall bladder, and, not being able to find it, they simply removed the appendix. An incision in the lower abdomen would be somewhat against that explanation. An 18-cm incision is somewhat in favor of it. It would be helpful to know whether or not she had any abnormality of the gall bladder. Apparently, we will not find out until Dr Mallory tells us.

So far as the terminal illness goes, I think there can be little question that this patient died of diffuse fibrosis of the liver — cirrhosis of some type. Perhaps it would be wiser simply to let it go at that. I do not believe that we can be very far wrong with such a diagnosis, but I think it is of some interest to speculate about the type of fibrosis or cirrhosis that this patient had, even at the risk of being wrong. I do not believe the terminal illness was due to infectious hepatitis — that is, it was not the type of hepatitis about which we customarily speak, a viral hepatitis. That may sound like a plausible explanation on first glance because most of the findings here are consistent with an acute hepatitis that began seven or eight weeks before death. However, there are several striking objections to it. One is the presence of varices, and the second is the presence of spider telangiectases on the skin. The latter can develop much sooner than the former, but it is highly improbable that with a seven weeks' history of the ordinary infectious or viral hepatitis either one of these would have occurred.

DR MALLORY Kunkel² has reported the detection of spider angiomas in the course of hepatitis.

DR KRANES How long a course?

DR MALLORY In a few weeks' time.

DR KRANES I will have to retract then, but I find it difficult to make a diagnosis of viral hepatitis in the presence of varices, unless one wants to assume that the patient had a chronic disease of the liver and finally, as a terminal event, a superimposed viral hepatitis. I would prefer to make one diagnosis to cover the whole history. Can we do that with this history? I think we can. I think this represents the type of cirrhosis or fibrosis that one occasionally finds in patients with obstruction of the large bile ducts. It travels under a variety of names. In this hospital Dr Mallory refers to it as biliary cirrhosis. Professor Himsworth³ calls it cholangiohepatitis, which appeals to me more. It is the type of cirrhosis that occurs with intermittent obstruction of the large bile ducts and with concomitant cholangitis. I think it is highly probable that for many years this patient had some type of obstructive lesion in the large bile ducts. This is

usually due to stones, although not necessarily. It can sometimes follow an inflammatory stricture of the bile duct, and occasionally there are cases in which no obstructive lesions in the bile duct are found. I should think, however, with this history of repeated attacks of pain, that it is highly likely stones will be found, if not in the common duct, possibly in the hepatic ducts. The patient also had cholangitis as evidenced by the periodic attacks of fever, finally becoming much more marked toward the end. Occasionally these patients will have, and this patient may have had, a terminal illness, with supuration around the small bile radicles in the liver, as evidenced by high fever and extreme tenderness of the liver. Many of these patients in more acute phases have multiple abscesses in the liver.

There would be a number of objections to such an explanation. In the first place, it is extremely unusual to develop portal obstruction in this type of cirrhosis, and we have x-ray evidence that there was portal obstruction. Another possible objection is that the white-cell count was low, or normal. Were all the white-cell counts as low as the initial one?

DR MALLORY We have three recorded 4000, 5300 and 5000 — essentially normal.

DR KRANES It is pertinent to point out that with acute cholangitis the white-cell count often does not rise. What about the absence of jaundice? I think that is a serious objection. I would like to know whether after the attacks described there is any statement about the absence of jaundice. Apparently none was noted, but one would like to know if there were any changes in the color of the stools or urine following attacks. Here, again, it is of some interest to point out that in this type of cirrhosis we have seen a small group in which no jaundice has ever appeared and the etiology is quite obscure.

Can we consider any other type of lesion in this patient? I hardly think so, although if this patient had a diseased gall bladder for twenty years, one must mention the possibility of carcinoma of the gall bladder. I can see nothing in the record that permits one to make such a diagnosis. So, I shall end up by saying that this patient had cirrhosis of the liver and by guessing that the cirrhosis was probably of the type I have mentioned.

A PHYSICIAN May I ask if there is any significance attached to the white-cell count of 4000?

DR KRANES I was unable to attach any significance to the white-cell count. The fact that there was a mild leukopenia was in favor of acute viral hepatitis. However, I find it hard to accept that diagnosis.

DR ANDRIES QUERIDO Although the age of the patient is much against the portal form of cirrhosis, would not the severe attacks simulating gall-bladder colic make one consider this form?

DR KRANES That is an interesting point and one that I should have brought out in the discussion. During the course of the ordinary portal cirrhosis, one occasionally sees patients with severe attacks of upper abdominal pain — and sometimes right-upper-quadrant pain — mimicking biliary colic in many respects, and at autopsy there appears to be no morphologic explanation.

DR KRANES I was unable to attach any significance to the white-cell count. The fact that there was a mild leukopenia was in favor of acute viral hepatitis. However, I find it hard to accept that diagnosis.

DR ANDRIES QUERIDO Although the age of the patient is much against the portal form of cirrhosis, would not the severe attacks simulating gall-bladder colic make one consider this form?

remained rigid, especially in the right upper quadrant. The blood sodium had risen to 128 milliequivalents per liter.

An operation was performed.

DIFFERENTIAL DIAGNOSIS

DR FRANCIS D MOORE* I should like to know what the rectal examination showed with reference to the prostate and also what the urinary sediment showed.

DR TRACY B MALLORY The prostate was not enlarged or tender. Examination of the urinary sediment on admission was negative. That is the only comment we have — just negative.

DR MOORE This case is important from the point of view of time relations. I should like to review them before going into the details of the history. The patient apparently entered the hospital with a past history of both urinary and gastrointestinal symptoms. The urine culture was negative despite the gross urinary sediment found on cystoscopy, so we must assume that that was a laboratory error and that the patient's urine was not normal. When the cystoscope was first put in there was fibrin which is seen in the urine in cystitis and is accompanied by a high white-cell count in the sediment. Cystoscopy was done on the sixth day, and on the twelfth day a subtotal gastrectomy was carried out. Following that he had ten days of uneventful convalescence except for continuation of the urinary-tract infection. That is important because a patient who has had ten days of smooth convalescence after subtotal gastrectomy should rightfully be considered to be beyond the point where one could expect a blow-out either of the duodenal stump or of the other suture lines. Yet this time is too short for the development of a jejunal ulcer, so the interval is of some help to us. On the eleventh postoperative day things began to pile up. The x-ray examination showed delay at the gastric cardia, spasm and tenderness of the abdomen on the twelfth day, severe abdominal pain on the thirteenth day, and a distended abdomen on the fourteenth day.

As I see it there are two problems in this case. One is the nature of the renal lesion, the second is the nature of the intra-abdominal complications of the gastrectomy. He was fifty-one and a painter. When Dr Aub looked at the protocol he immediately assumed that this was the case he was to

discuss. The question of lead poisoning must be considered as a possibility in the background.

His illness began at twenty-six, which is the characteristic age for the onset of duodenal ulcer symptoms. X-ray studies revealed a duodenal ulcer at that time. I assume that the treatment of duodenal ulcer twenty-six years ago — as at present — consisted largely of diet. The patient became asymptomatic rapidly, again characteristic of duodenal ulcer in the young adult male. One year later he discontinued his diet, and since that time he had had intermittent recurrence of mild to moderate distress. It would be interesting and important to know what he did when his distress came back. Did he treat himself with alkali? Here is a patient with severe kidney disease. We wonder if he took calcium in the form of milk or powders or did he just avoid rich foods?

Twenty-four years later, he began to have obstructive symptoms. He was admitted to the hospital with genuine obstruction — I say "genuine" since he lost 10 pounds in weight. This history is quite consistent in itself with the history of duodenal ulcer, and I see no reason to doubt that diagnosis or to take any further time discussing it. The report was "healing duodenal ulcer." This is interesting because it suggests a little difficulty for the surgeon in doing a gastrectomy, which is significant when we later pause to consider possible complications.

Did the patient have pyelonephritis or tuberculosis of the urinary tract? Restricted fluid intake, alkali therapy and exacerbation of urinary-tract infection are all factors that might have correlated a flare-up of renal disease with a flare-up of his ulcer symptoms. Frequency, burning and nocturia all point to the bladder and were certainly marked features of his symptomatology previous to admission. Whether he had chronic Bright's disease or pyelonephritis secondary to intravesicular obstruction we do not know from the evidence. When he came in, vital signs were normal and the chemical studies were essentially normal, but he had a low phenolsulfonphthalein excretion — it was 33 per cent in two hours. So this man's many years of renal difficulty had left him with definite impairment of renal function. The specific gravity of 1.015 is of possible interest — since he came in with vomiting and was mildly dehydrated. What was the red-cell count?

*Surreon-12-Chief, Peter Bent Brigham Hospital

count was 6800. The urine showed a specific gravity of 1.015 and was normal.

A roentgenogram of the chest revealed some evidence of emphysema and fibrosis. A gastrointestinal series showed a severe, constricting deformity of the duodenal cap within which an ulcer crater could be seen. An intravenous pyelogram disclosed slight blunting and rounding of the calyces on the right as well as slight dilatation of the pelvis.

Cystoscopy performed six days after admission demonstrated normal bladder mucosa except for many small pieces of fibrin. Both ureters were easily viewed. The right ureter discharged small pieces of fibrin. The retrograde pyelogram showed some pelvic sacculation, but the calyces appeared sharp. After the cystoscope had been passed a large amount of cloudy urine was obtained, especially in the final dregs. A culture taken at the time of cystoscopy was later reported as showing no growth.

After cystoscopy the patient was noted to have difficulty in voiding. This symptom persisted. On the second day following cystoscopy he was given 2 gm of sodium sulfadiazine in 1500 cc of 10 per cent dextrose and water. On the next day a closed bladder drainage was established. The phenol-sulfonphthalein test at this time showed 18 per cent excretion of the dye in fifteen minutes and 50 per cent excretion at the end of two hours. On the following day he was found to have a temperature of 103°F (it had previously been normal). Examination of the urine revealed a +++ test for albumin, and the sediment contained 40 to 60 white blood cells and 20 to 30 red blood cells per high-power field. A urine smear showed scattered gram-negative rods and abundant colon bacilli. The white-cell count was 11,000. The nonprotein nitrogen was 29 mg per 100 cc. The daily dose of 2 gm of sulfadiazine had been continued, and twenty-four hours later the temperature was normal and remained there. Three days later a subtotal gastrectomy was performed. His postoperative condition was considered good. A subsequent pathological report disclosed a healing duodenal ulcer.

On the third postoperative day the urine was loaded with white blood cells, and a culture was positive for *Bacillus pyocyaneus* (*Pseudomonas aeruginosa*). The temperature was normal, however. The nonprotein nitrogen was 26 mg, and the total protein 5.9 gm per 100 cc, and the chloride 98 milliequiv per liter. He was continued on 2.5 gm

of sodium sulfadiazine daily. Ten days after operation he was ambulatory, and he was taking a six-meal bland diet without difficulty. A blood sulfadiazine level was found to be 12.5 mg per 100 cc, after which the dose was reduced to 0.5 gm daily. On the following day, after a severe chill, the temperature rose to 103°F. He had difficulty voiding and complained of slight burning. There was no costovertebral-angle tenderness. The urine was loaded with white blood cells and bacteria. A gastrointestinal series showed some delay in the passage of barium at the gastric cardia. He was started on penicillin and streptomycin. During the next twenty hours the urinary output was about 250 cc. The temperature had remained at 103°F, and the white-cell count was 19,200. At this time the patient appeared very toxic. His face was flushed, and there was mottled cyanosis of the skin of the trunk and extremities. Respirations were rapid, and the pulse was 110. The blood pressure was 68 systolic, 40 diastolic. There seemed to be some spasm and tenderness in the right upper quadrant. The abdomen had a doughy feeling. Slight right-costovertebral-angle tenderness was also noted. An abdominal paracentesis later the same day produced only 5 cc of cloudy, nonodorous fluid. A smear showed many white cells. A culture was later reported to have grown nonhemolytic streptococcus and a questionable beta-hemolytic streptococcus. In an eleven-hour period following this the urinary output was about 30 cc. Examination revealed a +++ test for albumin, and the sediment contained countless white blood cells and red blood cells, but no crystals. (The urine became grossly bloody.) Study of the blood disclosed a nonprotein nitrogen of 67 mg and a total protein of 4.7 gm per 100 cc, a chloride of 83 milliequiv and a carbon dioxide of 14.6 milliequiv per liter and an amylase of 31 units and a sulfadiazine level of 8 mg per 100 cc.

In an effort to restore the electrolyte balance he was given hypertonic saline solution following which his condition seemed to improve. However, later the same day he complained of episodes of severe abdominal pain, recurrent in nature, with pain-free periods in between. The abdomen was rigid, silent and tender. The white-cell count was 15,400, and the temperature 101°F. A blood culture was later reported as positive for *B. pyocyaneus*.

On the following day he seemed considerably improved although he remained oliguric. The abdomen

be The blood sulfadiazine level was 12.5 mg per 100 cc, and along with 250 cc of urine a day there is no question that he was running a real risk of precipitation of this drug in the kidneys. The patient began to look toxic, and the blood pressure dropped. A flushed face and a high temperature may be due to kidney disease, but the mottled cyanosis and the blood-pressure drop are, in my experience, less commonly associated with an exacerbation of pyelonephritis. There seems to have been spasm in the right upper quadrant — something beginning to develop in the abdomen — despite the fact that it was twelve days after operation. Then toxemia developed, and there was a doughy feeling in the abdomen, and some distention — a characteristic finding in tuberculous peritonitis. The abdominal tap yielded only 5 cc of white, malodorous fluid. I wondered why they used the word "only." I would put an exclamation mark after this because it is difficult to obtain much fluid by tap. Usually with localization it is walled off, it is difficult to get much material by aspiration of a peritonitis.

Then the urinary output dropped even more — 30 cc in eleven hours. The urine became grossly bloody for the first time, and the blood chemical findings markedly abnormal. The nonprotein nitrogen was 67 mg per 100 cc, and the total protein dropped to levels that in the laboratories of this hospital are definitely compatible with an accumulation of edema. The chloride was 83 milliequiv, and the carbon dioxide 14.6 milliequiv per liter — in other words, total anions were depressed, with definite acidosis. I would just assume that the sodium was also very low. What was the sodium?

DR STANBURY: About 115 milliequiv per liter.

DR MOORE: The sulfadiazine level got down to 8.0 mg per 100 cc after the dose had been reduced to 0.5 gm. Did he have sulfonamide crystals in the urine? An effort was made to restore the chloride with saline solution. The situation was ripe for such therapy: plasma chloride is responsive to the use of hypertonic solutions. He developed more pain, recurring at intervals and suggesting smooth-muscle cramps. The blood culture was positive for *B. pyocyaneus*. I do not know how to interpret that, I doubt if it was the organism in his blood. The change from 115 to 128 milliequiv per liter in the blood sodium was due presumably to the concentrated saline solution.

Were the oliguria and anuria due to pyelonephritis from an ascending infection? Ulcer patients form stones and pass them from time to time, and this might have been the background. As a matter of fact 4 or 5 per cent of patients who come to surgery for duodenal ulcer will have a history of having passed renal stones. This patient did not, but that would be a logical background for pyelonephritis in this case. As far as the abdomen is concerned, the most likely bet is that he developed an abscess around the duodenal stump. This development was masked by sulfonamide, penicillin and streptomycin therapy. Toward the end of the history the abscess got larger, and we might hypothesize that it ruptured into the general peritoneal cavity — general peritonitis and obstruction. A great many things are against that duodenal-stump difficulty after ten days of apparently uneventful convalescence is rare. That brings it up to the second possibility, that he did not have peritonitis but that the malodorous abdominal fluid was a case of mistaken identity. The needle might have got into some viscus, possibly the bladder. His signs and symptoms may have been due entirely to renal disease. Ileus, cramps and distention can be seen not only in renal colic but also in kidney failure. The third possibility is that the abdominal picture and the renal disease were both on the same basis, and the only way I can tie them together is by the diagnosis of tuberculosis. If this patient had renal tuberculosis, we might assign it as the cause of the urinary symptoms and suggest that after a subtotal gastrectomy, for some reason, he developed tuberculous peritonitis.

We have three sets of diagnoses, and which shall I take? The safest bet is to take the commonest, although that is not the most intriguing possibility, and say that he had pyelonephritis, with renal failure, probably on the basis of stones, possibly made worse by the precipitation of sulfonamide in the kidney, and to account for the abdominal symptoms, a leak at the duodenal stump with the development of an abscess. Having taken what I think is the best bet, I shall hand Dr. Mallory an apple.

DR STANBURY: I saw this man two days before operation. At that time the problem as outlined was mainly one of renal failure, sepsis and disturbed electrolyte balance.

DR MALLORY No red-cell count is given

DR MOORE The total protein was 6.6 gm per 100 cc — suggestive of dehydration in a thin, depleted man. He should have been able to concentrate better than 1.015.

Let us have a look at all three sets of x-ray films at one time.

DR STANLEY M. WYMAN The films of the chest show no demonstrable gross abnormality. One film taken from the intravenous-pyelogram examination is poor because of the large amount of overlying gas in the large bowel. However, one can see that at fifteen minutes the contrast substance appeared in good concentration in both kidney pelves and calyces. Other films taken at this examination are less satisfactory. The pelvis of the right kidney is definitely somewhat wide, and the major calyces are wide. The minor calyces are not adequately seen, but I can demonstrate no gross blunting or lack of cupping. It is interesting that the bladder shadow is distended at this time, and as yet no dye has appeared in the bladder. The retrograde pyelogram done four days later again shows the rather large bladder, which may be a result of cystoscopy. I believe the pelves and major calyces are slightly widened on the right and perhaps even a little on the left.

DR MOORE Would you describe the kidney findings as compatible with a diagnosis of tuberculosis of the upper urinary tract?

DR WYMAN I do not think the evidence for tuberculosis is here unless it is in one minor calyx at the lower pole of the right kidney, which shows a narrow band of constriction. I can see this on no other film. It may be a chance result of muscle contraction at this time. I would hesitate to make a diagnosis of tuberculosis on the films available.

DR MOORE The course of the ureter does not seem abnormal?

DR WYMAN The course is normal, the ureter is a little bit wide. It is interesting that with withdrawal of the catheter from the left kidney there was a suggestion of blunting in the lower pole, which raises the question of an aberrant vessel or possibly, and less likely, a stricture. The gastrointestinal series before operation demonstrates the duodenal cap with a crater. The film taken after subtotal gastrectomy shows the gastric remnant and anastomosis of the jejunum.

DR MOORE What about the cystoscopy? I have already brought out that we cannot blame the urinary disease on cystoscopy. It antedated it since small pieces of fibrin were coming out of the right ureter. All that means is that the inflammatory process was above the bladder.

Then we move on to the institution of sulfadiazine therapy, which comes along through the rest of the history. There are two or three things of interest about it. Here is a patient with kidney disease (although at the time it was not certain how serious a factor it was going to become) who was given a drug that in the presence of oliguria might well have precipitated in the kidney. We should like to know if there were any casts in the sediment. Yet the nonprotein nitrogen stayed down, and the sulfadiazine was continued. I can well imagine the thoughts on the Surgical Service: Should they go ahead or wait? He was not taking oral feeding. Parenteral alimentation could not replace oral feeding indefinitely, and the surgeon probably wanted to get him over to oral intake. The temptation to open his alimentary canal was overwhelming, and despite the risk of gastrectomy they decided to go ahead with operation.

At first the patient did well. The temperature was normal. "He was continued with 2.5 gm of sulfadiazine." Was that by mouth or by vein?

DR JOHN B. STANBURY Both.

DR MOORE That is important. In a patient given sulfadiazine orally, after subtotal gastrectomy one cannot be confident of the degree of absorption in the postoperative period. But if the drug is given by vein, it gets into the body fluids and, therefore, is capable of producing difficulty in the kidneys. It is interesting that ten days after operation he was up and around, getting 2.5 gm a day, 2.5 gm is not a large dose, but the blood sulfadiazine level was 12.5 mg per 100 cc. That must have disturbed the Service, since he was not excreting the drug properly even with a small dose. Whereupon the temperature went up, apparently because of urinary difficulty. The urine sediment continued to be loaded with white cells and bacteria. A gastrointestinal series was taken and he was started on penicillin and streptomycin. This is interesting because this combined therapy is capable of masking a great deal that is going on in the abdomen. The urinary output was only 250 cc, approximately a fifth of what the Service would have liked it to

"LEARNED ART AND PUBLIC SERVICE"

ROSCOE POUND in his address delivered at the annual dinner of the Massachusetts Medical Society in May and published as the leading article in this issue of the *Journal* describes clearly the position of the professions in the society of today.

Popular ideas of a profession are somewhat confused by the modern meaning of professionalism in its relation to athletics. Preferable to the concept of professional as used in apposition to amateur is that of a profession consisting of "a group of men pursuing a common calling as a learned art and as a public service."

A heritage of the Middle Ages, this pattern is the one in which medicine, the law, the ministry and teaching have developed and achieved their stature. Other important callings have come in recent years to be considered among the professions, being of much the same substance, "as learned arts,

taught in universities and pursued in a tradition of learning." Such are journalism, engineering, business administration, social work and public administration.

For many the idea of ethics helps to distinguish the profession, since ethics is implicit in its pursuit—not that a trade cannot and should not be ethically conducted, but its primary object is commercial. Three ideas, according to Dean Pound, are essential in a profession: organization, learning and the spirit of public service—to which he later adds a code of ethics. The earning of a living in a profession does not detract from its concept but may be curbed by the professional spirit.

This also is implicit in professional organization, that professional societies and associations exist only for the purpose of protecting and improving the standards of service, not for the benefit of the persons practicing the profession. If benefit accrues to the practicing personnel it follows naturally on an improvement in the quality and the conditions of the practice.

In America, Dean Pound points out the pioneer forefathers distrusted specialists in any line and put their faith in the versatility that had been so essential to their own success. This was to the detriment of the professions. Deprofessionalization was part of the creed of the frontier, which has made necessary a reprofessionalization during the last two generations.

The world moves on. As American political thought breaks away from its fear of governmental oppression of the individual, new pressures are appearing. From four sources in today's society the professional ideal is being threatened. These are the exigencies of the individual economic existence, which is always present, the increase in detail in every branch of learning, leading of necessity to partnerships and groupings, the pressure of business methods, and eventually the advent of the service state and "the growing tendency to rely on official rather than on individual private initiative and to commit all things to bureaus of politically organized society."

Here is the great menace to the professional ideal—"the development of great government bureaus and a movement to take over the arts prac-

DR MOORE Two days before the final operation?

DR STANBURY Yes From the chart, as we saw it, it seemed obscure About forty-eight hours before the final operation, he really began to get into trouble He was up and about during that time, and we have no way of knowing whether the sulfonamide was being precipitated

DR MOORE Do you see renal difficulty due to precipitation of sulfonamides in the kidney tubules without any crystals coming down into the urine?

DR STANBURY Usually we see the crystals

DR MOORE Lower-nephron nephrosis after transfusion without hemoglobinuria?

DR MALLORY I would say almost certainly no to both questions

DR ALLAN M BUTLER Sulfonamide reaction can occur in the absence of crystals in the urine

DR STANBURY We were concerned with the electrolyte balance Dr Jack Crawford helped us on that The patient was moribund, and Dr Crawford brewed us a solution of hypertonic saline and lactate, which was given every two hours with dramatic improvement The cyanosis disappeared, the respirations improved, and the patient looked better

DR MOORE Did the renal output improve after the hypertonic infusion?

DR STANBURY Not appreciably

DR BUTLER Did the blood pressure improve?

DR STANBURY Yes We thought along with the surgeons that he had sepsis in the right upper quadrant

CLINICAL DIAGNOSES

Pyelonephritis, *B pyocyaneus*

Peritonitis, acute

Septicemia, *B pyocyaneus*

DR MOORE'S DIAGNOSES

Pyelonephritis with renal failure, caused by renal stones and possibly sulfonamide nephrosis

Abdominal abscess at site of gastrectomy

ANATOMICAL DIAGNOSES

Pyelonephritis, severe, *B pyocyaneus*

Operation subtotal gastric resection for duodenal ulcer

PATHOLOGICAL DISCUSSION

DR MALLORY At the time of exploration no gross peritonitis could be found and no evidence of any localized sepsis The patient died shortly after operation

DR MOORE Did he have anything at that exploration to correlate with the 5 cc of purulent fluid?

DR MALLORY A small amount of slightly cloudy fluid was found, nothing else At autopsy our findings were similar The peritoneum contained a slight amount of fluid, a little old fibrin and no evidence of acute peritoneal reaction and no localized sepsis The stomach and the resection lines in the stump of the duodenum were perfectly adequate Our only important finding at autopsy was in the kidneys, which showed extremely severe, extensive pyelonephritis Cultures from them showed a pure culture of *B pyocyaneus* I think the finding of *B pyocyaneus* in the blood stream ante mortem was unquestionably due to septicemia It is an organism of low virulence and on frequent occasions has been observed to go with septicemia We did not find any other organisms in the kidneys It was not possible, in the face of severe, acute reaction in the kidneys, to say with any definiteness whether there was longstanding pre-existing pyelonephritis Everything was obscured by the intense reaction, and the renal substance consisted almost entirely of a mass of focal abscesses There were a few old calcium spicules scattered here and there in the renal parenchyma, which probably went back to the alkali therapy

DR MOORE It might be worth while to say that the hunch, that the ten-day period of convalescence really did have significance, was correct I think that is an important point

DR MALLORY Yes

Report in its entirety — that a wedge has been driven in that will split the recommendations of the Commission from stem to stern

Such an interpretation, however, need not be given major consideration. The Commission itself was by no means emphatically in favor of the department of welfare and gave at least partial support to the idea of a separate department of health. The argument of the proponents of the plan, that the Administration's proposals should have been accepted at the time and corrected later if necessary, by the separation of the department into those units that would function best independently of each other, presented a species of reasoning that scarcely needed to be taken seriously. Eggs are not thus easily unscrambled, nor can an ambitious department head, should such a one be chosen, be expected to give up any part of his authority without a struggle.

A POOR SHOWING

IN THE Massachusetts Medical Society section of this issue of the *Journal* a statement appears from Dr George F Lull, secretary of the American Medical Association, regarding the twenty-five-dollar assessment that was levied upon the members last winter. The Massachusetts Medical Society, with only 49 per cent of its own membership responding, stands in forty-second place among the fifty-three constituent associations that make up the parent organization.

There are various reasons for this absolute and relative delinquency. A number of the fellows of the Society are financially unable to meet the assessment, and no pressure is being put upon them to pay. The Society does not ask any fellow to assume an undue burden on this account. With many, however, it is believed to be a matter of principle, real or apparent, that although they are opposed to compulsory federal health insurance, they are even more opposed to the methods of the American Medical Association in combating it and will have no part in such an undertaking.

These physicians are urged to see the problem as a whole, one in which they are all involved, and one in which minor grievances and criticisms of methods

should not stand in the way of the larger principles at stake. Such a plea is not directed to those few doctors who are honestly and earnestly in favor of compulsion. Their principles are respected as all honest principles should be. Otherwise the situation appears to be one in which an association of physicians in need of funds, levies an assessment on its membership, as provided in its by-laws. Approximately half the members from one state, still retaining their membership, neglect to pay.

There are times when Massachusetts may well be proud to stand with a courageous minority instead of with a mistaken majority. Is there any evidence that this is one of them?

A physician from Westchester, N Y, has established himself on the banks of the Sacramento, in a log cabin, one-half of which he uses as a store and the other as a hospital, and it is said that he receives as much gold daily as the average of twenty miners.

Boston M & S J, September 5, 1949

MASSACHUSETTS MEDICAL SOCIETY

A M A ASSESSMENT

On August 2, 1949, the following statement was received from Dr George F Lull, secretary of the American Medical Association:

As of July 28, 1949 our records show that your association had remitted 49% of the twenty-five dollar assessment. Its relative standing in percent collected among the 53 constituent societies is 42.

There are fellows of this society who, for one reason or another, cannot meet this assessment, but if we are not to appear in such a dismal light, surely 80 per cent of our membership should meet the obligation.

Recently the district secretaries have been given the lists of fellows in their districts who have not yet paid this contribution to the Educational Campaign.

It is hoped that personal contacts in the various districts will bring the desired result.

ticed by the professions and make of them *functions* of the government to be exercised by its bureaus in a super-service state that may become a service super-state." It is not the idea of the service state that is repugnant, for welfare services that ameliorate the lot of many persons must continue. It is the difficulty of maintaining a balance between individual initiative and regimented co-operation. Majority dictation must not be revered.

"The service state," Dean Pound is willing to concede, "is a political step forward. But we must not let it turn back upon itself and lead us to absolutism. There is no surer road to absolutism than an unchecked omniscient bureaucracy."

Freedom is not a natural state for man, which rushes in wherever a political vacuum exists. It must be fought for, cherished and guarded, against threats from within as well as from without. It is based on tolerance, which is one of the rarest social and political attributes. Nowhere has true democracy, now in jeopardy, been more subtly defined than in a quotation from the essayist, E. B. White, published in the *Harvard Alumni Bulletin*:

"Democracy," according to this definition, "is the recurrent suspicion that more than half of the people are right more than half of the time."

HEALTH UNIT BILL BECOMES LAW

THE Union Health Bill, enabling all towns and cities of Massachusetts to form union health departments, was signed by Governor Dever on August 10. Such combinations at a community level actually add strength to decentralization in government, long a New England tradition but unique in present political procedures.

The Commonwealth of Massachusetts entered early the field of public health with the establishment of the first board of health in Boston in 1799. Seventy years later the first state department of health in the country was established in Massachusetts, a delayed result of Lemuel Shattuck's famous survey. This early entry into the field gave rise, however, to the acceptance of methods and traditions that, though outworn, have survived to the present day. Systems of organization that were suited to the relative isolation of communities and

the slow rate of travel of another century are not adapted to cope with the increased populations and the mobility of today.

Under the circumstances that at present prevail, each of the 351 cities and towns of the Commonwealth has its own board of health, with no health officer at all in 113. Only a few communities have joined forces in providing a better grade of public-health services for themselves, as has been done through the Nashoba Health Unit. The new law, called by Dr. Vlado A. Getting, commissioner of public health of Massachusetts, "the most important health legislation that has been passed since the establishment of our State Department of Health in 1869," removes the barriers that have prevented the people of Massachusetts from having all the available advantages of public-health protection.

The Act makes possible the formation generally of units such as that which exists in the Nashoba area, headed by full-time medical directors chosen by the union boards of health. The need was emphasized in the 1948 Recess Commission Report to the Massachusetts General Court, which recommended full-time union health departments for each 35,000 population group in the State.

Through these units the advantages of immunization of pre-school children, pre-natal advice to mothers, well-child conferences, inspection of private water supply and sewage systems, chest x-ray examination and the control of communicable disease can be brought to the people of the Commonwealth wherever they may live.

Through better health services for all the people will come one of their best defenses against the extension of sickness taxation at any level.

DEFEAT OF PLAN 1

THE rejection by the United States Senate last month of Reorganization Plan 1, the proposal for an all-inclusive department of welfare, has resulted in considerable lamentation and some recrimination from friends and foes of the Administration alike. The most serious criticism of the Senate vote and the most apparently logical one appears to be that the rejection of this initial fractional reorganization plan represents a potential rejection of the Hoover

Report in its entirety — that a wedge has been driven in that will split the recommendations of the Commission from stem to stern

Such an interpretation however need not be given major consideration. The Commission itself was by no means emphatically in favor of the department of welfare and gave at least partial support to the idea of a separate department of health. The argument of the proponents of the plan, that the Administration's proposals should have been accepted at the time and corrected later if necessary, by the separation of the department into those units that would function best independently of each other, presented a species of reasoning that scarcely needed to be taken seriously. Eggs are not thus easily unscrambled, nor can an ambitious department head should such a one be chosen, be expected to give up any part of his authority without a struggle

"The service state," Dean Pound is willing to concede, "is a political step forward. But we must not let it turn back upon itself and lead us to absolutism. There is no surer road to absolutism than an unchecked omniscient bureaucracy."

Freedom is not a natural state for man, which rushes in wherever a political vacuum exists. It must be fought for, cherished and guarded, against threats from within as well as from without. It is based on tolerance, which is one of the rarest social and political attributes. Nowhere has true democracy, now in jeopardy, been more subtly defined than in a quotation from the essayist, E. B. White, published in the *Harvard Alumni Bulletin*:

"Democracy," according to this definition, "is the recurrent suspicion that more than half of the people are right more than half of the time."

HEALTH UNIT BILL BECOMES LAW

THE Union Health Bill, enabling all towns and cities of Massachusetts to form union health departments, was signed by Governor Dever on August 10. Such combinations at a community level actually add strength to decentralization in government, long a New England tradition but unique in present political procedures.

The Commonwealth of Massachusetts entered early the field of public health with the establishment of the first board of health in Boston in 1799. Seventy years later the first state department of health in the country was established in Massachusetts, a delayed result of Lemuel Shattuck's famous survey. This early entry into the field gave rise, however, to the acceptance of methods and traditions that, though outworn, have survived to the present day. Systems of organization that were suited to the relative isolation of communities and

the slow rate of travel of another century are not adapted to cope with the increased populations and the mobility of today.

Under the circumstances that at present prevail, each of the 351 cities and towns of the Commonwealth has its own board of health, with no health officer at all in 113. Only a few communities have joined forces in providing a better grade of public-health services for themselves, as has been done through the Nashoba Health Unit. The new law, called by Dr. Vlado A. Getting, commissioner of public health of Massachusetts, "the most important health legislation that has been passed since the establishment of our State Department of Health in 1869," removes the barriers that have prevented the people of Massachusetts from having all the available advantages of public-health protection.

The Act makes possible the formation generally of units such as that which exists in the Nashoba area, headed by full-time medical directors chosen by the union boards of health. The need was emphasized in the 1948 Recess Commission Report to the Massachusetts General Court, which recommended full-time union health departments for each 35,000 population group in the State.

Through these units the advantages of immunization of pre-school children, pre-natal advice to mothers, well-child conferences, inspection of private water supply and sewage systems, chest x-ray examination and the control of communicable disease can be brought to the people of the Commonwealth wherever they may live.

Through better health services for all the people will come one of their best defenses against the extension of sickness taxation at any level.

DEFEAT OF PLAN 1

THE rejection by the United States Senate last month of Reorganization Plan 1, the proposal for an all-inclusive department of welfare, has resulted in considerable lamentation and some recrimination from friends and foes of the Administration alike. The most serious criticism of the Senate vote and the most apparently logical one appears to be that the rejection of this initial fractional reorganization plan represents a potential rejection of the Hoover

The highest prevalence so far has been in the Boston metropolitan area and toward the north shore

The incidence of measles was the lowest in forty years. Scarlet fever was at the lowest level ever recorded for July

GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Diphtheria was reported from Beverly, 1, Boston, 14, Chelsea, 2, Danvers, 1, Leominster, 2, Malden, 3, Medford, 1 total, 24

Dysentery, bacillary, was reported from Boston, 1, total, 1
Encephalitis, infectious, was reported from Swansea, 1 total, 1

Tetanus was reported from Taunton, 1, total, 1
Typhoid fever was reported from Boston, 2, Leominster, 1, Winthrop, 1, Worcester, 3, total, 7

Undulant fever was reported from Boston, 1, Douglas, 1, Medway, 1, New Marlboro, 1, total, 4

MISCELLANY

ANGIOLOGY

Angiology, The Journal of Peripheral Vascular Diseases, will begin publication in February, 1950. Dr. Saul S. Samuels, chief of the Department of Peripheral Arterial Diseases, Stuyvesant Polyclinic, New York City, will be editor-in-chief. Among the associate editors in the United States will be Dr. Alton Ochsner, of Tulane University; Dr. Keith Grimson, of Duke University; Dr. Leo Loewe, of Long Island Medical College; Dr. D. W. Kramer, of Jefferson Medical College; and Dr. Gerald Pratt, of New York University Medical School.

The new journal will be published by the Williams and Wilkins Company, of Baltimore.

CORRESPONDENCE

JARISH-HERXHEIMER REACTION QUESTIONED

To the Editor: There is considerable question in my mind concerning the case report by Dr. Diefenbach in the July 21 issue of the *Journal*, entitled "Fatal Jarish-Herxheimer Reaction with Sudden Aneurysmal Dilatation and Complete Bronchial Occlusion Following Penicillin Therapy." There is no question that the patient died of bronchial obstruction fifty-seven days after the institution of therapy, but whether the penicillin therapy had any causal relation remains unproved; it seems to me Jarish-Herxheimer reactions usually occur within the first twenty-four to forty-eight hours, and there usually is associated fever, which was absent in this case after the institution of penicillin.

I am a little disappointed to see the *New England Journal of Medicine* publish a report about which, there seems to me, to be so much question.

JAMES H. CURRENS, M.D.

Boston

Dr. Currens's letter was submitted to Dr. Diefenbach who offers the following reply:

Penicillin therapy was instituted late on the first hospital day and x-ray study of the chest showed a clear left-lung field. Thirty-six hours after the administration of penicillin there was sudden dyspnea with all signs of complete obstruction of the left main bronchus, confirmed by bronchoscopy and roentgenogram.

Although it is true that the patient did not expire immediately the fact remains that a Jarish-Herxheimer reaction had occurred and that he subsequently died of a suppurative pneumonia.

WILLIAM C. L. DIEFENBACH, M.D.
Englewood, New Jersey

BOOK REVIEWS

Child Health Services and Pediatric Education. Report of the Committee for the Study of Child Health Services. The American Academy of Pediatrics. With the co-operation of the United States Public Health Service and the United States Children's Bureau. 8°, cloth, 270 pp. New York: The Commonwealth Fund, 1949. \$3.50.

The Committee for the Study of Child Health Services of the American Academy of Pediatrics has recently completed a three-year nationwide survey of the services and facilities available for the medical care and health supervision of infants and children. This survey included also a study of the training in pediatrics that the physicians who provided this care had received both general practitioners and pediatricians, and the opportunities for education in this field now offered by medical schools and hospitals. The book gives the findings of this survey in summary and graphic forms and the Committee's interpretation of these findings. A supplemental report, *Methodology and Tabulations on Services*, also published by the Commonwealth Fund, will be released shortly for those who wish to study the data in greater detail. These two volumes constitute the final report of this national committee and of the survey on a nationwide basis.

This study was initiated by and conducted throughout under the leadership and direction of the American Academy of Pediatrics, its representative, Dr. John P. Hubbard, serving as director. It was carried out with the technical aid and full co-operation of the United States Public Health Service and the United States Children's Bureau. Without the able assistance of Dr. Katherine Bain, of the Children's Bureau, and Mr. Rollo Britten and Mrs. Maryland Pennell, of the United States Public Health Service, this report would not have been possible. The Committee and its large staff were also aided by many national, state and local groups concerned with the care of children, as well as by a large number of practicing physicians, dentists and other persons, who made the required information available. It was accomplished at a cost of \$1,000,000 provided collectively by several foundations and commercial houses, as well as by the American Academy of Pediatrics and the National Institute of Health. This is the first time that a comprehensive study of medical services to children has been made in the United States, and it is gratifying that it has been done by the national organization of physicians best qualified to deal with the health problems of children. It is of interest that this organization was able to obtain the very general co-operation of the practicing physicians of the country and that it received at its own request extensive assistance from two governmental agencies equipped through national experience and statistical facilities to meet many of the basic needs for such a project.

Massachusetts physicians have been well represented among the leaders of this project of the Academy at the national level. Dr. Warren Sisson served as chairman of the National Committee, and Dr. John Hubbard, its executive secretary, was in charge of its large staff in Washington. Dr. Lendon Snedeker acted during the survey as regional representative of the central office and now is executive secretary to the Massachusetts Committee, which is preparing the report for this state. Dr. James Wilson is chairman of the Committee for the Improvement of Child Health Services. All of these are now or were formerly Boston pediatricians. The Committee for the Study of Child Health Services now has completed its authorized undertaking, and the Committee for the Improvement of Child Health Services will for-

DEATHS

Boos — William F. Boos, M.D., of Fall River, died on August 11. He was in his eightieth year.

Dr. Boos received his degree from Harvard Medical School in 1901. He was medicolegal expert for the federal Government and the Commonwealth of Massachusetts and for many years was toxicologist for the Suffolk County medical examiner. He was a fellow of the American Medical Association.

His widow and two daughters survive.

Dunn — William A. Dunn, M.D., of Boston, died on July 15. He was in his eighty-first year.

Dr. Dunn received his degree from New York University Medical College in 1893. He was formerly police surgeon and physician at the Boston prison and House of Detention. For twenty-five years he served as assistant to the medical examiner of Suffolk County.

Emery — William C. Emery, M.D., of Dorchester, died on August 20. He was in his seventy-sixth year.

Dr. Emery received his degree from Harvard Medical School in 1909. He was a fellow of the American Medical Association.

His widow and two sons survive.

Reagh — Arthur L. Reagh, M.D., of West Roxbury, died on June 15. He was in his seventy-ninth year.

Dr. Reagh received his degree from Harvard Medical School in 1898.

Robinson — Henry A. Robinson, M.D., of Hingham, died on August 21. He was in his third year.

Dr. Robinson received his degree from Harvard Medical School in 1911. He was a member of the New England Pediatric Society.

His widow, a daughter, his father and a brother survive.

Story — Theodore L. Story, M.D., of Southbridge, died August 9. He was in his sixty-second year.

Dr. Story received his degree from Tufts College Medical School in 1917. He was a fellow of the American Medical Association.

His widow, a brother and two grandchildren survive.

Tierney — Thomas F. Tierney, M.D., of Hudson, died July 24. He was in his seventy-third year.

Dr. Tierney received his degree from Baltimore Medical College in 1901. He was a fellow of the American Medical Association.

Two sons, a daughter and a brother survive.

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

NITRITE POISONING IN INFANTS

From various places in the country come reports of acute illnesses, mostly in young children or infants, that have been traced to drinking of waters high in nitrates. The illness is marked by a blue color of the skin with rapid recovery when the source of water is changed. Unless properly diagnosed and treated, however, the disease is by no means to be lightly regarded. Some reports indicate a mortality of 10 per cent.

The apparent explanation for the difficulty lies in the young infant's inability to break down satisfactorily the nitrates into ammonia. The resultant nitrites combine with hemoglobin to form methemoglobin.

Arthur D. Weston, C.E., director of the Division of Sanitary Engineering, Massachusetts Department of Public Health, has investigated Massachusetts waters and reports that in recent years the highest yearly average nitrate content of any public water supply in the Commonwealth has in only one case exceeded 10 parts per million, a concentration believed to be the upper limit of safety. This was exceeded by the semi-public supply of Whately (Craft Springs) in 1943, 1944 and 1945, when it was found to be 17.1, 20.8 and 13.0 parts in a million, respectively.

Considerably higher nitrate content has been reported, however, in this state in waters of rural water supplies such as the "farm well."

No cases of methemoglobinemia have been reported thus far to the Department of Public Health as chargeable to water supplies in this state. Precise information is needed to disclose the minimum concentration of nitrates in waters that have actually caused cases of methemoglobinemia among infants.

The Massachusetts Department of Public Health would welcome notification by physicians of any cases of methemoglobinemia. The Department will arrange for examination and analysis of water used in connection with the feeding of these infants.

PREVALENCE OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR JULY, 1949

DISEASE	RÉSUMÉ		
	JULY 1949	JULY 1948	SEVEN YEAR MEDIAN
Chancroid	3	4	2 ^a

Whooping cough	387	130	

*Five year median

COMMENT

Diseases above the seven-year median were diphtheria, dog bite, German measles, mumps, poliomyelitis, pulmonary tuberculosis and typhoid fever.

Diseases below the seven-year median were chicken pox, bacillary dysentery, malaria, measles, meningococcal meningitis, salmonellosis, scarlet fever, undulant fever and whooping cough.

Diphtheria was still unusually prevalent for this time of year. Although the incidence of German measles and mumps was higher than the seven-year median, both diseases occurred much less often than in the previous month.

The incidence of poliomyelitis reported for the month of July was the highest it has been in the last three decades.

Writing as a lover of the Italian land and people, the author has correlated with data from the classics some of the information that he has gathered during years of acquaintance with many parts of the Italian peninsula and of Sicily, and from a lifetime of reading in the voluminous literature in various languages about their inhabitants. But his comparison of two widely separated periods of that people's history is more than "a loving likelihood," for he finds not only that many pagan practices and superstitions persist in combination with Christian custom but also that identical beliefs, charms, drugs, exorcisms, herbs, incantations, spells and talismans that were employed by Romans twenty centuries ago are still used among their peasant descendants of today. Even the Phi Beta Kappa key has been mistaken as some sort of American amulet. Much folk medicine is based on sympathetic magic, on the familiar principle of *similia similibus curantur*.

This volume, which is abundantly documented by a bibliography of 350 references to classical and modern literature, is an invaluable treasury of interest to gynecologists, obstetricians and pediatricians, as well as to students of the classics and of folklore and folkways. It is a humanistic work of well directed research and of profound scholarship.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Which Way Out: Stories based on the experience of a psychiatrist By C. P. Oberndorf, M.D. 8°, cloth, 236 pp. New York: International Universities Press, Incorporated, 1948. \$3.25.

In this volume the author presents eleven fictional stories, with the object of portraying different psychopathic personalities. None of the stories are depictions of true experiences. The publishing is well done in every way.

A Synopsis of Physiology By A. Rendle Short, B.Sc., M.D., F.R.C.S., C.L.G. Pratt, O.B.E., M.A., M.D., M.Sc., lecturer in mammalian physiology, University of Cambridge, and fellow of Christ's College, Cambridge, and C. C. N. Vass, M.Sc., Ph.D., M.B., Ch.B., reader in physiology in the University of London. Fourth edition. 12°, cloth, 346 pp., with 23 illustrations. Baltimore: Williams and Wilkins Company, 1948. \$6.00.

The authors have completely revised and completely rewritten some sections to bring the manual up to date since the publication of the third edition in 1938. The object of the book is to give a fairly full summary of modern physiology, especially human, in a small space. For beginners the synopsis should be used in conjunction with textbooks on physiology, including biochemistry and experimental physiology, and histology. The text was printed in Great Britain. The number of editions speaks well for the soundness of the book.

Recent Advances in Respiratory Tuberculosis By Frederick Heaf, M.A., M.D., F.R.C.P., senior medical officer, London County Council, honorary medical director, British Legion Village, Preston Hall, Kent, and consulting physician, Papworth Village Settlement, and N. Lloyd Rusby, M.A., D.M., F.R.C.P., assistant physician, the London Hospital, physician, the London Chest Hospital, and consulting physician to the British Legion Sanatorium, Preston Hall, and the National Sanatorium, Benenden. Fourth edition. 12°, cloth, 290 pp., with 5 plates and 7 text-figures. Philadelphia: Blakiston Company, 1948. \$5.50.

The authors in this fourth edition, first published in 1929 and later in 1931 and 1937, by the late Dr. L. S. T. Burrell, have brought the material up to date. They believe that the environmental and social aspects of tuberculosis have become very important during the last decade, and for the first time have included chapters on these aspects. The material on public-health services, including legislation, is based on British practice. Considerable space is devoted to artificial

pneumothorax and collapse therapy. A list of selected references is appended to each subject. The text was printed in Great Britain, and the volume is well published. It should prove useful as a reference source.

Essentials of Gynecologic Endocrinology (with Sections on the Male) By Gardner M. Riley, Ph.D., assistant professor of obstetrics and gynecology, University of Michigan Medical School 8°, paper, 205 pp., with 31 illustrations. Ann Arbor, Michigan: Caduceus Press, 1948. \$3.00.

The author, in this manual, presents the fundamentals of reproductive physiology, the endocrine aspects of gynecologic dysfunction and details of useful procedures. The material is based in a large part upon the lectures and discussions prepared for the Gynecology Endocrine Conferences of the Department of Obstetrics and Gynecology of the University of Michigan Medical School. The book is designed for medical students, interns and physicians who have to deal with gonadal function in the male or female. The text is divided into three parts: endocrine physiology, clinical material, and diagnostic procedures, sex-hormone chemistry and endocrine preparations. There is a special chapter on the endocrinology of the male. The material is well organized. A list of selected references is appended to each chapter. There is a good index, and the volume is well published by the offset process. The book should prove useful as a compend in the subject.

Common Skin Diseases By A. C. Roxburgh, M.A., M.D., B.Ch. Cantab., F.R.C.P., consulting physician and lecturer, St. John's Hospital for Diseases of the Skin, and dermatologist to the Royal Masonic Hospital. Eighth edition. 8°, cloth, 497 pp., with 212 illustrations. Philadelphia: Blakiston Company, 1948. \$7.00. *General Practice Series*.

This textbook, a part of the *General Practice Series*, has an interesting history, speaking well for its soundness. It was first published in 1932, and since then has appeared in eight editions and seven reprints, making a total of fifteen issues. In addition the eighth edition was translated into French in 1948. The book which is intended for the general practitioner, discusses the important phases of diagnosis and treatment, with special emphasis on differential diagnosis. This last edition has added the use of penicillin and DDT in dermatology. The text has been revised and brought up to date, the latest knowledge on various skin diseases being incorporated. Whatever references are used are interspersed throughout the text. There is a good index. The text was printed in Great Britain with a good type on good paper. A heavy paper was necessary for the illustrations, and it is evident that a sufficient supply was found for this edition. The binding is well done. It is interesting to note that the Blakiston Company has entered the business of importing the pages of a book, and binding and distributing in the United States. Although reflecting the British point of view, the book should be in all medical libraries and prove useful to the general practitioner.

Anesthesia: Principles and Practice. A presentation for the nursing profession By Alice M. Hunt, R.N. 12°, cloth, 148 pp. New York: G. P. Putnam's Sons, 1949. \$2.60.

This manual is written for nurses, and Miss Hunt places the emphasis on the patient and not on the surgeon and writes accordingly. She is well qualified in her subject, since she was attached for twenty-five years to the Yale University School of Medicine and the New Haven Hospital. A graduate of the School of Nursing of the Union Hospital at Fall River, she began the study of anesthesia at the Truesdale Hospital in the same city, where she became head of the nursing service. She later became head of the service at the Peter Bent Brigham Hospital in Boston, from where she went to the New Haven Hospital as chief of the service. She became a member of the faculty of Yale University School of Medicine and was retired on July 1, 1948, with the rank of associate professor of anesthesia, emerita. After a short historical chapter, the book discusses the physiology and general methods, followed by the different anesthetics and the special methods of anesthesia. There is a selected bibliography and a good index. The manual is well published and should prove useful, not only to nurses but also to physicians.

mulate recommendations designed to correct the deficiencies described in the present report.

This book provides a welcome opportunity to shift the base of discussions of medical needs from broad, undocumented generalizations to sound data applicable to the situations under consideration. Upon such facts alone can a satisfactory program for the improvement of child care be constructed, and the Academy may be justly proud of its leadership in obtaining them. It is unfortunate that comparable information respecting the medical care of other age groups has not been assembled under the leadership of the medical profession so that all discussions of medical care could be approached in the same way.

A unique feature of this report is its excellent condensation and presentation of a large number of data. The charts are expertly constructed to reveal the essential facts, unnecessary tables and statistical compilations have been strictly eliminated. The text is also brief and readable and well correlated with the charts, highlighting them without undue repetition. As a result, the reader is hardly aware of the enormous number of statistical analyses dealt with.

The report is presented in three parts: child health services, pediatric education, and a general summary. In the first part the introductory statements about the technical aspects of the study itself are commendably brief, and the summaries of findings by region, race, density of population, age and economic group begin to occupy the reader's attention in the first chapter. These summaries include data on births, deaths, hospital facilities and amounts of medical, dental and other health services available for each group considered. They show that children in or near cities receive far more medical care, more specialists' services and better hospital and clinic facilities than children living away from cities. They show, furthermore, that community health services do not fill the gaps in medical care for those unable to obtain it privately. For example, 2000 counties in the United States, representing 31 per cent of the children under five years of age, have no well-child conference for those unable to obtain health supervision otherwise. Only 6 per cent of the children in the country as a whole attend such conferences. Health services for school children are found to be almost as inadequate. Variations between the states and their local subdivisions in amounts and kinds of services generally are tremendous.

The second part of the report gives an excellent picture of the extent of training or, more properly, the inadequacies of training in pediatric subjects provided in connection both with undergraduate medical education and with graduate education in hospitals. It shows clearly that present educational facilities do not provide general practitioners the training in child care that they require. Almost half the general practitioners have had little hospital training in pediatrics, and yet three quarters of the private care of children is in their hands.

The character and the extent of the deficiencies in medical care and health services for children throughout the United States and in pediatric education have been clearly revealed by this over-all report. A brief review of the findings in their broad perspective is presented in the third part, which focuses attention on the principal deficiencies. Each of the New England states may determine from this national report its standing among the states and comparable communities in the availability to children of the various services studied and to some extent their quality. The supplementary volume referred to will give more of the crude data for further use by those concerned with development of plans, and the data themselves have been returned to each state and are available to local agencies for further study.

It is not possible in this review to summarize for all types of service the positions held by each New England state in relation to other states or to the national average. The regional summarizations in the report group the New England with the North Central states, and the average ratings for this group of very dissimilar communities are not very informative concerning the situation in any one. The findings for these states are generally favorable in relation to most other regions, and, in some respects, they are outstanding. However, the individual New England states show sharp individual differences as well as local area differences by counties or health districts. Information was made available to Massachusetts on the basis of its public-health districts by special arrangement because the county data were not

found satisfactory for use in this state. Individual states in the New England area are to be found in the lowest as well as in the highest categories in some ratings—for example, that for infant mortality. So, also, a high state rating for a given service—for example, the number of physicians available per thousand children—may go hand in hand with the finding that certain communities within the state lack available physicians' services.

Among generally favorable circumstances in the New England states may be mentioned the following three of the states are in the highest category for number of hospital beds reserved for children. Some of these beds, obviously, are available to children from other states, which, in part because of this, maintain fewer beds for children. The children in all the New England states, except one, have more physicians available and receive more medical care generally and more hospital care specifically than the average for the country as a whole. Children in all these states are also relatively well provided with dental care. All these states exceed the national average in the percentage of births occurring in hospitals, Connecticut having the highest percentage for any state and Massachusetts holding fourth place. On the whole, the record for this region, as revealed by this study, is an excellent one. It offers the best available evidence of the advanced development of medical services in some of the New England states. As in the rest of the country, the local situations that are out of tune with this general picture appear to depend more upon the extent of urbanization of the area than upon state lines. This is particularly true of medical care and is less applicable to health services such as well-child conferences and public-health nursing services, which more clearly reflect state planning. The amount of the physician's time devoted to the various services for well children varies tremendously, being related in part at least to the number of physicians per unit of population.

Physicians will not all agree about the significance to the children concerned of some of the ratings assigned to their communities on the basis of the data obtained in the survey. They will all find it a stimulating undertaking, however, to look at the facts and to attempt to interpret them objectively. No one is better fitted to interpret the facts than the physicians in the community to which the specific ratings apply. The next step obviously is for each state and local community to study its own problems in the light of this revealing information, and all physicians concerned with the care of children will be interested in such an analysis. The progress that is made as a result of this study will depend in no small measure upon the extent to which physicians generally acquaint themselves with the facts, both from the national report and from the studies of local findings. The considered actions that they take individually and collectively to improve local situations will have much to do with the character and effectiveness of this progress.

Each state committee of the Academy is responsible for the report of the findings for its state and for recommendations based upon them. The state chairmen for New England are as follows: Maine, Dr Thomas A. Foster; New Hampshire, Dr Cohn C. Stewart, Jr.; Vermont, Dr Paul D. Clark; Massachusetts, Dr James M. Baty; Rhode Island, Dr William P. Buffum; and Connecticut, Dr J. Howard Root. Some state committees have already published reports, but others are still occupied with this large undertaking. The report for Massachusetts is nearing completion and will be available for general distribution early in the fall. Massachusetts is fortunate in having had other studies in progress during the past two or three years that supplement the Academy study and provide a far more adequate body of knowledge than is ordinarily available when a program for improvement of services is being developed.

Conception, Birth and Infancy in Ancient Rome and Modern Italy. By Walter B. McDaniel. 8°, cloth, 77 pp. Lancaster, Pennsylvania: Business Press, Incorporated, 1948.

This monograph, recently given by its author, a distinguished American classical scholar, to the Boston Medical Library, presents the result of his prolonged, painstaking observation and research in the fields of folk medicine and comparative literature. It is a study of the popular beliefs, practices and superstitions relating to conception, pregnancy, childbirth and infancy among the ancient Romans and among their heirs and racial descendants in modern Italy.

Writing as a lover of the Italian land and people, the author as correlated with data from the classics some of the information that he has gathered during years of acquaintance with many parts of the Italian peninsula and of Sicily and from a lifetime of reading in the voluminous literature in various languages about their inhabitants. But his comparison of two widely separated periods of that people's history is more than a loving likelihood, for he finds not only that many pagan practices and superstitions persist in combination with Christian custom but also that identical beliefs, charms, drugs, sorceries, herbs, incantations, spells and talismans that were employed by Romans twenty centuries ago are still used among their peasant descendants of today. Even the Phi Beta Kappa key has been mistaken as some sort of American amulet. Much folk medicine is based on sympathetic magic, on the familiar principle of *similia similibus curantur*.

This volume, which is abundantly documented by a bibliography of 350 references to classical and modern literature, is an invaluable treasury of interest to gynecologists, obstetricians and pediatricians, as well as to students of the classics and of folklore and folkways. It is a humanistic work of well directed research and of profound scholarship.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

What May Out: Stories based on the experience of a psychiatrist By C. P. Oberndorf, M.D. 8°, cloth, 236 pp. New York: International Universities Press, Incorporated, 1948. \$3.25.

In this volume the author presents eleven fictional stories, with the object of portraying different psychopathic personalities. None of the stories are depictions of true experiences. The publishing is well done in every way.

A Synopsis of Physiology By A. Rendle Short B.Sc., M.D., F.R.C.S., C.L.G. Pratt O.B.E. M.A., M.D., M.Sc., lecturer in mammalian physiology, University of Cambridge, and fellow of Christ's College, Cambridge, and C.C.N. Vass M.Sc., Ph.D., M.B., Ch.B., reader in physiology in the University of London. Fourth edition. 12°, cloth, 346 pp., with 23 illustrations. Baltimore: Williams and Wilkins Company, 1948. \$6.00.

The authors have completely revised and completely rewritten some sections to bring the manual up to date since the publication of the third edition in 1938. The object of the book is to give a fairly full summary of modern physiology, especially human, in a small space. For beginners the synopsis should be used in conjunction with textbooks on physiology, including biochemistry and experimental physiology, and histology. The text was printed in Great Britain. The number of editions speaks well for the soundness of the book.

Recent Advances in Respiratory Tuberculosis By Frederick Heaf, M.A., M.D., F.R.C.P., senior medical officer, London County Council, honorary medical director, British Legion Village, Preston Hall, Kent, and consulting physician, Papworth Village Settlement, and N. Lloyd Rusby, M.A., D.M., F.R.C.P., assistant physician, the London Hospital, physician, the London Chest Hospital, and consulting physician to the British Legion Sanatorium, Preston Hall, and the National Sanatorium, Benenden. Fourth edition. 12°, cloth, 290 pp., with 5 plates and 7 text-figures. Philadelphia: Blakiston Company, 1948. \$5.50.

The authors in this fourth edition, first published in 1929 and later in 1931 and 1937, by the late Dr. L. S. T. Burrell, have brought the material up to date. They believe that the environmental and social aspects of tuberculosis have become very important during the last decade, and for the first time have included chapters on these aspects. The material on public-health services, including legislation, is based on British practice. Considerable space is devoted to artificial

pneumothorax and collapse therapy. A list of selected references is appended to each subject. The text was printed in Great Britain and the volume is well published. It should prove useful as a reference source.

Essentials of Gynecologic Endocrinology (with Sections on the Male) By Gardner M. Riley, Ph.D., assistant professor of obstetrics and gynecology, University of Michigan Medical School. Paper. 205 pp. with 31 illustrations. Ann Arbor, Michigan: Caduceus Press, 1948. \$3.00.

The author, in this manual, presents the fundamentals of reproductive physiology, the endocrine aspects of gynecologic dysfunction and details of useful procedures. The material is based in a large part upon the lectures and discussions prepared for the Gynecologic Endocrine Conferences of the Department of Obstetrics and Gynecology of the University of Michigan Medical School. The book is designed for medical students, interns and physicians who have to deal with gonadal dysfunction in the male or female. The text is divided into three parts: endocrine physiology, clinical material, and diagnostic procedures: sex-hormone chemistry and endocrine preparations. There is a special chapter on the endocrinology of the male. The material is well organized. A list of selected references is appended to each chapter. There is a good index and the volume is well published by the offset process. The book should prove useful as a compend in the subject.

Common Skin Diseases By A. C. Roxburgh, M.A., M.D., B.Ch. Cantab., F.R.C.P., consulting physician and lecturer, St. John's Hospital for Diseases of the Skin and dermatologist to the Royal Masonic Hospital. Eighth edition. 8°, cloth, 497 pp. with 212 illustrations. Philadelphia: Blakiston Company, 1948. \$7.00. General Practice Series.

This textbook, a part of the *General Practice Series*, has an interesting history, speaking well for its soundness. It was first published in 1912 and since then has appeared in eight editions and seven reprints, making a total of fifteen issues. In addition the eighth edition was translated into French in 1948. The book, which is intended for the general practitioner, discusses the important phases of diagnosis and treatment with special emphasis on differential diagnosis. This last edition has added the use of penicillin and D.D.T. in dermatology. The text has been revised and brought up to date the latest knowledge on various skin diseases being incorporated. Whatever references are used are interspersed throughout the text. There is a good index. The text was printed in Great Britain with a good type on good paper. A heavy paper was necessary for the illustrations, and it is evident that a sufficient supply was found for this edition. The binding is well done. It is interesting to note that the Blakiston Company has entered the business of importing the pages of a book, and binding and distributing in the United States. Although reflecting the British point of view, the book should be in all medical libraries and prove useful to the general practitioner.

Anesthesia: Principles and Practice: A presentation for the nursing profession By Alice M. Hunt, R.N., 12°, cloth, 148 pp. New York: G. P. Putnam's Sons, 1949. \$2.60.

This manual is written for nurses and Miss Hunt places the emphasis on the patient and not on the surgeon and writes accordingly. She is well qualified in her subject since she was attached for twenty-five years to the Yale University School of Medicine and the New Haven Hospital. A graduate of the School of Nursing of the Union Hospital at Fall River, she began the study of anesthesia at the Truesdale Hospital in the same city where she became head of the nursing service. She later became head of the service at the Peter Bent Brigham Hospital in Boston, from where she went to the New Haven Hospital as chief of the service. She became a member of the faculty of Yale University School of Medicine and was retired on July 1, 1948, with the rank of associate professor of anesthesia, emeritus. After a short historical chapter, the book discusses the physiology and general methods, followed by the different anesthetics and the special methods of anesthesia. There is a selected bibliography and a good index. The manual is well published and should prove useful not only to nurses but also to physicians.

How To Live Longer By Justus J Schifferes With a foreword by Ralph F Sikes, M.D. 8°, cloth, 255 pp New York E P Dutton and Company, Incorporated, 1949 \$3.00

Mr Schifferes, formerly a teacher of health education and hygiene at Columbia University and Teachers College, organizer and director of the Health Education Council, co-founder of the periodical *Modern Medicine* and its editor for ten years, has written a popular manual on the prevention of the great common diseases of mankind. The volume is not a "home medical handbook", it does not diagnose illnesses or prescribe treatment. It endeavors to point out the warning signs in time for proper therapy to be instituted. The text is written in simple, nontechnical language and is based on the latest information on public health and on the latest United States Government statistics. It discusses the "Big Killers"—heart disease, cancer, stroke, kidney disease, accidents, pneumonia, tuberculosis, premature birth, diabetes, suicide and syphilis. The chapter entitled "Little Danger Signals" is very valuable and should be available to the entire population of the country. The final chapter comprises a list of health-promoting organizations and their publications. There is a good index. The type, printing and paper are excellent for this type of book, which should be in all public libraries and in the popular section of medical libraries.

Your Coughs, Colds and Wheezes By Joseph D Wassersug, M.D. 12°, cloth, 277 pp New York Wilfred Funk, Incorporated, 1949 \$2.95

In this book for the laity the author discusses the common cold, its prevention and treatment and the various respiratory diseases. Dr Wassersug is a competent authority on chest diseases and enjoys a wide experience in that field. The text is well written but seems a little too technical in certain places for the general reader.

ANNOUNCEMENT

Dr S Brodie announces the opening of his office for the practice of pediatrics at 238 North Main Street, Fall River, Massachusetts

94TH INFANTRY DIVISION LECTURES

The 94th (Bay State) Infantry Division is sponsoring a series of monthly lectures by prominent physicians in their respective specialties. The sixth lecture will be held in the auditorium of Boston University School of Medicine, 80 East Concord Street, Boston, on Wednesday, September 28, at 8 p.m.

Dr William L Fleming will speak on the subject "Present Status of Penicillin Therapy in Syphilis."

All interested physicians, whether reserve officers or not, are cordially invited to attend this carefully planned program. Reserve officers will be given one point credit if authorized by the instructor of their unit of assignment. Excellent films will also be shown during this period.

Number 11

SPONTANEOUS PERFORATION OF THE ESOPHAGUS

Report of Three Cases Successfully Treated Surgically

JOSEPH P. LYNCH, M.D.*

BOSTON

SPONTANEOUS perforation of the presumably normal esophagus has been considered a rare lesion. A recent increase in the number of reports on this subject indicates that it may not be as unusual as was formerly believed. Barrett,¹ Olsen and Clagett² and Kinsella³ have recently considered this subject so completely that further review is unnecessary. The original, classic description of the lesion by Boerhaave in 1723 and the first diagnosis made during life by Walker⁴ in 1914 represent historical milestones. In modern times, the diagnosis has been made before death a number of times, but seldom early enough to permit treatment. Recent advances in thoracic surgery, as well as the development of the antibiotics, have made it possible to treat such patients successfully when the diagnosis is made early. Therefore, an awareness of this lesion and its characteristic symptomatology becomes increasingly important.

Spontaneous perforation differs from other types of perforation of the esophagus. In traumatic perforations the history of aspiration of a foreign body or a previous operative manipulation serve to focus attention on the esophagus. Occasionally, a peptic ulcer of the esophagus perforates and the history is similar to that of patients with spontaneous perforation. However, the history of previous symptoms of ulcer should make one suspicious of the underlying cause. Since the pre-existing ulcer usually sets up a reaction in the mediastinum, perforation is generally directly into the pleural cavity, with the formation of a hemothorax, an infrequent occurrence in spontaneous perforation of the esophagus.

In most of the cases of spontaneous perforation of the esophagus described in the literature, there has been no background in the history that would lead one to suspect disease of the esophagus. Furthermore, since most cases occur during vomiting there is immediate flooding of the mediastinum with

the highly irritant gastric contents. This gives rise to the characteristic symptoms usually noted, which are seldom present when the perforation is traumatic.

Commonly, the history is one of a patient vomiting for one of many reasons—most frequently after a bout of alcohol ingestion. In the course of vomiting, and usually after severe retching, there has been sudden severe pain, usually referred to the precordium or epigastrium or both. This pain is generally associated with a shock reaction, dyspnea and, at times, cyanosis. The physician first seeing the patient frequently considers coronary thrombosis the most likely diagnosis although including the possibility of a perforated gastric ulcer. The blood pressure is low, the pulse is rapid, the temperature is subnormal, and there may be upper abdominal tenderness and spasm. These signs usually continue for the first few hours after onset. The blood pressure gradually rises but generally remains at a lower than normal level. The temperature rises, and signs of a pleural effusion develop. This occurs almost always on the left but has occasionally developed on the right. Within six to twelve hours of onset, air may be palpable in the neck, and this, with the previous history, is diagnostic of perforation of the esophagus. From the history, one should always suspect the condition in any patient who has sudden severe epigastric or precordial pain that comes on during vomiting.

Since most patients are hospitalized almost immediately because of the severe nature of their illness, and since perforated ulcer is suspected, it is usual to have an x-ray examination of the abdomen in a search for subphrenic air. Such a procedure can be most helpful in the diagnosis, since air behind the heart is frequently seen and is one of the most characteristic findings. Even in the early stages, a small pleural effusion has been noted. The usual chest x-ray film at this time may also show air in the upper mediastinum. Under the circumstances here described, such a finding is diagnostic.

*Visiting surgeon for thoracic surgery, St. Elizabeth's Hospital and Massachusetts Memorial Hospitals; consultant in thoracic surgery, Carney Hospital.

Untreated, the course is progressively downhill, and the majority of patients have died within forty-eight hours of the onset of the lesion.¹ There are described in the literature 2 cases in which a localized empyema or mediastinal abscess developed, the perforation of the esophagus closed spontaneously, and recovery followed drainage of the empyema or mediastinal abscess.⁶ Such a localization must be rare, the usual outcome of esophageal perforation being one of diffuse mediastinal infection that is rapidly fatal. Attempts to drain the local infection by mediastinotomy or pleural drainage during the acute stage have generally been unsuccessful.^{1, 6}

Moore and Murphy⁷ have recently reported an unusual case treated conservatively. After walled off had occurred, thoracotomy repair was successful. These authors suggest the use of the conservative measures of pleural drainage and jejunostomy, believing that, in many cases, the perforation will heal spontaneously. In the cases in which healing does not occur, operative intervention can be undertaken.

There are certain similarities in the development of this lesion to that of perforated peptic ulcer, and in a general way, one believes that correction of this defect should follow the same lines as the treatment of perforated peptic ulcer. It appears necessary that adequate drainage of the mediastinum, with closure of the perforation, be provided. Ideally, this is accomplished by thoracotomy, wide opening of the mediastinal pleura, closure of the esophageal defect, re-expansion of the lung and closure of the chest, with intercostal tube drainage. Attempts at such a procedure have been made by various surgeons. Collis⁸ and Foggett⁹ completed their operations successfully, but the patients died a few hours later. Kinsella's³ patient was well on the road to recovery, only to die of a pulmonary embolism on the ninth postoperative day. More recently, Barrett¹⁰ and Olsen and Claggett² have treated patients definitively with success.

The decision to undertake operation for such patients is not simple. These patients are acutely ill, their blood pressure is extremely low, and they are poor candidates for anesthesia. However, since the results without surgical repair are so disastrous, operation is justified despite the patient's condition at the time the patient is first seen. Obviously one first prepares the patient, as necessary, by thoracocentesis, gastric suction and transfusions. However, delay longer than a few hours will permit further deterioration of the patient's condition.⁶ One can be encouraged by the fact that immediately after opening of the mediastinal pleura, the patient should be considerably improved by relief of mechanical compression of mediastinal structures. In Case 2 reported below, the blood pressure remained at shock levels until the chest cavity was entered and the mediastinal pleura opened, the tension

within the mediastinum thus being relieved. From that time, the patient's blood pressure remained normal throughout the operation. This same sequence of events was also true in Barrett's¹⁰ successfully treated case.

CASE REPORTS

CASE 1 H M, a 45-year-old man, was admitted to the Mount Auburn Hospital on July 11, 1947, because of severe pain in the upper abdomen and lower chest. The patient had always been well until 3 months prior to admission, when he began to have dizzy spells, for which his physician was unable to find a cause. On the night of July 11, the patient felt nauseated and vomited. Because the feeling of nausea persisted, he attempted to make himself vomit. During one of these attempts, there was a sudden onset of severe pain in the left anterior portion of the chest and upper abdomen. The pain was unbearable from its onset, and a physician was called immediately. When seen, the patient was in shock, the temperature was subnormal, and the pulse 110. He was immediately sent to the hospital with a tentative diagnosis of coronary thrombosis.

At the time of admission, electrocardiogram and x-ray films of the abdomen were normal. A chest plate at that time (Fig. 1) showed a slight amount of fluid at the left base.

FIGURE 1 Posteroanterior Roentgenograms of the Chest on Admission in Case 1, Showing a Small Amount of Fluid at the Left Base

Twenty-four hours after admission, x-ray study revealed a pleural effusion filling the left side of the chest (Fig. 2). At that time the blood pressure was normal, the temperature was 100°F, and the pulse 110, and he was relatively comfortable. During the next 24 hours, the patient's condition deteriorated gradually, and a thoracic surgeon was consulted. Physical examination at that time showed that the trachea was deviated to the right. There was subcutaneous emphysema in the right supraclavicular fossa. The entire left side of the chest was flat to percussion, and the breath sounds were absent. The abdomen was voluntarily spastic, without tenderness or palpable masses.

A diagnosis of spontaneous perforation of the esophagus, with rupture of the mediastinal abscess into the pleural cavity, was made. Review of the previous x-ray films showed air present in the mediastinum (Fig 2)

Thoracentesis was performed immediately, and 500 cc. of seropurulent fluid was removed. Direct smear showed gram-positive cocci, culture of which later proved to be pneumococci. Because of the patient's poor condition and the fact that the lesion had been present for approximately 60 hours, radical operation was not considered. Intercostal drainage was accomplished, 1500 cc of purulent fluid being removed, after which the breath sounds were well heard throughout the left side of the chest. Penicillin and streptomycin were given in large doses. On the following day, the patient's condition was satisfactory, the tube was functioning well. There appeared to be atelectasis of the left lung, and endotracheal suction was performed, with immediate expansion of the lung. Constant gastric suction was instituted, and the patient was

FIGURE 2 *Posteroanterior Roentgenogram of the Chest Twenty-Four Hours after Admission in Case 1*

The left side of the chest is filled with fluid, and air can be seen in the upper mediastinum and neck

maintained on intravenous administration of fluids and transfusions

One week after admission, the patient's condition remained satisfactory, and a swallow of radio-opaque oil was given. This showed a definite perforation at the lower end of the esophagus, with the oil in the mediastinum and communicating with the pleural cavity.

On July 22 a rib-section drainage of the empyema was performed, and through the empyema cavity, a large mediastinal abscess was opened into the pleural cavity. Subsequently, the patient's condition appeared to become worse. There was considerable mobility of the underlying lung, and toxicity seemed to increase greatly. There was frequent regurgitation of gastric contents through the perforation into the empyema cavity. Such an incident usually coincided with a marked elevation of temperature. This was controlled by gastric suction. A jejunostomy was performed for feeding.

Four attempts to repair the linear laceration of the esophagus which was easily seen at the bottom of the empyema cavity, were made at intervals of 10 to 14 days, without success in spite of what appeared to be a completely adequate three-layer closure of the esophagus. The patient's condition gradually improved, and after these failures, no further attempts to close the esophagus were made. The patient was allowed up and about, and gradually, over a period of 1 month after the last attempt at closure, the laceration in the esophagus closed and he was able to take food by mouth.

He was discharged home on November 4, 1947, with a jejunostomy tube in place, the empyema cavity widely opened, and moderate amounts of food being taken by mouth. The patient's condition gradually improved at home. The empyema wound closed. The jejunostomy tube was withdrawn, and approximately 1 year after the original perforation, he was eating normally and was working full time. Operative closure of a persistent jejunostomy fistula was necessary 1½ years after the original episode.

Because the perforation had existed sixty hours before diagnosis, it did not appear that the patient's condition would allow a major surgical procedure at that time. Therefore, temporary drainage of the pleural cavity was performed with an intercostal tube, and, later, wide-open drainage of the mediastinal abscess and empyema accomplished. For approximately three months, this patient was extremely ill—at times, even moribund. Repeated transfusions were necessary, he presented a problem of hydration and nutrition at all times. He lost a considerable amount of weight during the first two months, despite jejunostomy. Eventually adequate feedings could be accomplished and the weight was regained.

Bacteriologically, the only organism cultured from the mediastinal abscess or pleural fluid was a pneumococcus. The fact that this was the only organism present may have contributed to his ability to withstand the infection.

Attempts to close the esophagus within the empyema cavity, despite adequate technical closure, were completely unsuccessful, since the suture line was bathed in the empyema pus and sloughing occurred within forty-eight hours of the time of repair. Yet the patient's condition was never such that one would consider decortication of the empyema, closure of the esophagus, re-expansion of the lung and closure of the chest wall. All these procedures would have been necessary to produce definitive operative closure after the first month. Awaiting natural closure provided a successful, if long delayed, cure.

CASE 2 J. R., a 56-year-old man, was admitted to St. Elizabeth's Hospital on April 26, 1948, because of pain in the epigastrium and lower chest. For 2 days prior to admission, he had vomited intermittently without other symptoms. At 4:30 a.m. on the day of admission, he was suddenly awakened by nausea and vomiting. He vomited for approximately ½ hour, retching severely with the vomiting. Suddenly, during an attack of vomiting, he was seized with severe, excruciating pain in the lower chest and upper abdomen. At that time, examination of the chest and abdomen by his physician was negative. The patient was in moderate shock, the pulse was rapid, and it was the examining physician's impression that the patient had a penetrating ulcer. Morphine was ordered, and the patient was told to remain at rest. A few hours later, because the pain persisted, he was hospitalized.

Physical examination showed the patient to be in severe shock and obviously toxic. There was slight cyanosis of the face and neck. There was marked venous distention of the neck and arms, with some crepitation in the right supraclavicular area. Examination of the chest was essentially negative except for diminished breath sounds at the left base. The abdomen showed slight tenderness and spasm.

X-ray examination of the chest and upper abdomen revealed air in the mediastinum (Fig. 3 and 4), and the diagnosis of spontaneous rupture of the esophagus was made.

Operation was performed approximately 30 hours after the onset of pain. Under endotracheal nitrous oxide, ox-

saline solution, and the lung re-expanded. One hundred thousand units of penicillin and 1 gm. of streptomycin were left in the pleural cavity. A No. 28 catheter was inserted through the tenth interspace for drainage. The chest wall was closed in layers, with interrupted catgut sutures and black silk to the skin.

The immediate postoperative course was uneventful. There was moderate drainage for 48 hours, after which the drainage tube ceased to function. The lung was well expanded immediately postoperatively and remained so. The temperature became normal on the 2nd postoperative day. The tube was left in place for 8 days because of a small posterior collection of fluid. Penicillin was continued for 8 days, and streptomycin for 4 days.

Administration of liquids was started on the 2nd postoperative day, and soft solids on the 5th day. On the 8th day, a small amount of methylene blue was given in water, and after 1 hour, the drainage within the intercostal tube showed a blue coloration. Because of this, open drainage of the posterior collection of fluid was performed. Two days later, a jejunostomy was performed, and the patient was fed through this for 10 days. From that time on there was no evidence of esophageal leakage. The patient was allowed to have a normal diet and was discharged home on June 5.

FIGURE 3 Posteroanterior Roentgenogram of the Chest on Admission in Case 2, Showing Air in the Mediastinum and Neck

There is a small pleural effusion on the left

xygen and ether anesthesia, the blood pressure was 70/40. The pulse was of good quality and rapid, and the respirations were shallow. In the right lateral decubitus position, a 25-cm. oblique incision was made over the ninth rib, and very slight bleeding was encountered. A 25-cm. segment of the rib was removed, and the pleura was opened. The pleura was grossly discolored, appearing edematous and alternately black and gray. There were thick, black fibrin clots over the pleural surface, and there was a moderate amount of thin, gray, dirty, odorless fluid within the pleural cavity. The lung, which was loosely adherent to the diaphragm, was freed. The mediastinal pleura was bulging, and when it was opened, there was a gush of dirty gray fluid and air from the mediastinum. The mediastinum was then widely opened, and the fluid removed. At this point, the blood pressure returned to normal and remained so thereafter. At the lower end of the esophagus, approximately 1 cm. above the diaphragm on the left anterolateral wall, was a 5-cm. vertical laceration, which involved the muscularis and mucosal coats, the edges, however, appeared entirely normal except for the reaction similar to that present throughout the mediastinum. There was no evidence of ulceration or tumor or stricture above or below the point of perforation. The mucosa was inverted with a running 000 catgut suture. The muscular layers were closed with interrupted catgut sutures. The pleural cavity was then irrigated with physiologic

FIGURE 4 Posteroanterior Film of the Upper Abdomen Taken in the Upright Position on Admission in Case 2, Showing the Air in the Mediastinum behind the Heart

The jejunostomy tube was left in place for 1 month as a safeguard and then removed. The wound closed spontaneously. The empyema pocket closed rapidly, being completely obliterated in 6 weeks.

Postoperative follow-up study during the next 6 months showed no evidence of complications. The patient was eating well. There was no pain in the chest, the lungs were normally expanded, and the diaphragm functioned normally.

This case served to emphasize a number of points. The first, and most important, was that the diagnosis was made by the roentgenologist from the roentgenogram of the abdomen and chest. Nevertheless, it was not immediately appreciated that surgical treatment was possible, since it was believed

that this was a fatal lesion. However, the time allowed to pass was of no importance in this case, but the outcome could have been more serious if too much time had elapsed.

Secondly, the case showed, strikingly, the effect of mediastinal compression on the blood pressure. Immediately after the mediastinum was opened and the fluid and gas were released, the pressure returned to normal. It has been suggested^{1, 3} that the early deaths are due to the mechanical compression of the vascular structures in the mediastinum, relief of which can be accomplished only by open drainage of the mediastinum. A reperforation at the site of repair apparently occurred in Case 2, but healing was rapid once rib-resection drainage of the empyema had been accomplished and jejunostomy feeding started. Generally, the results of operation, although not definitive, were most satisfactory and within a month of the onset, the patient was eating normally.

CASE 3. J. R., a 62-year-old man, was admitted to the Carney Hospital on November 12, 1948, with a history of severe chest pain of approximately 12 hours' duration. The patient stated that on the previous day he had consumed

time, he noted some sweating. His physician was called immediately.

Examination of the chest was negative. There was some tenderness with a slight spasm in the epigastrium. The blood pressure was 120/60, with a pulse of 100. The physician was unable to make a definite diagnosis and the patient was given morphine for pain. Re-examination on the following morning showed a further fall of the blood pressure, with an increase in the tenderness and spasm of the epigastrium. At this time, there was some dullness with diminished breath sounds at the left base, and because of this, the patient was hospitalized.

After admission, the course remained essentially unchanged. The patient preferred to sit up in bed and had a grunting-type of respiration, and there was increased spasm of the upper abdomen that appeared to be voluntary in type. There was slight subcutaneous emphysema in the right supraclavicular fossa.

The temperature was 103°F, the pulse 110, and the blood pressure 110/60.

X-ray examination, performed to rule out a perforated ulcer, showed air behind the heart (Fig. 5). A film of the

FIGURE 5. *Posteroanterior Roentgenogram of the Upper Abdomen Taken in the Upright Position on Admission in Case 3. This film clearly demonstrates the air behind the heart.*

a large amount of beer while eating a moderate amount of food. At approximately 10 p.m. he noted severe gastric distress. Because of this distress, he attempted to vomit, and after some time, he had moderate success. He continued his efforts to make himself vomit, and during a period of severe retching, he suddenly noticed a burning sensation in the center of his chest. Because this sensation was so painful, the patient had to sit upright and lean forward. At the same

FIGURE 6. *Posteroanterior Roentgenogram of the Chest on Admission, Showing Air in the Lower Mediastinum.*

chest taken at the same time showed widening of the mediastinum, with air in the mediastinum up to the neck (Fig. 6). The diagnosis of spontaneous perforation of the esophagus was made, and a thoracic surgeon was consulted. Immediate operation was advised and performed 12 hours after the onset.

Under endotracheal nitrous oxide, oxygen and ether anesthesia, the left side of the thorax was entered through the bed of the ninth rib. Cloudy, odorless fluid was found when the pleural cavity was entered. The lung was retracted, and the mediastinum was seen to be bulging. Immediately on opening of the mediastinal pleura, air escaped, and a large amount of dirty, gray fluid that had a faintly foul odor was obtained. A large piece of cabbage was found in the mediastinum. At the lower end of the esophagus at the left anterolateral wall a 3.8-cm laceration of a linear type was found. The mucosa pouted through the muscularis and appeared normal. The esophagus was mobilized at this

area, and the perforation closed with interrupted No 000 silk sutures. The mucosa was closed in a double layer. A flap of mediastinal pleura was developed and sutured down over the area of laceration. The mediastinum was opened widely up to the arch of the aorta. The pleural cavity was irrigated with physiologic saline solution, and 100,000 units of penicillin and 1 gm of streptomycin were left in the pleural cavity. A No 28 catheter was inserted through the tenth interspace for drainage. The lung was re-expanded, the chest wall was closed in layers with interrupted No 00 catgut sutures. The skin was closed with black silk.

The postoperative course was uneventful. Intramuscular administration of penicillin and streptomycin was continued postoperatively for 5 days. The intercostal tube drained satisfactorily for 48 hours and was removed after 72 hours in spite of a small amount of fluid that remained at the base posteriorly. The temperature remained normal from the 3rd day after operation. The patient was allowed out of bed on the 4th day. He was placed on a liquid diet from the 3rd day on, and was given a soft-solid diet on the 6th day. The patient was discharged on the 14th hospital day on a normal diet. The course thereafter remained satisfactory, and examination approximately 4 months after operation showed him to be in good physical condition. The lung was well expanded, he was taking a normal diet without difficulty.

This case represented the ideal of definitive treatment of this serious condition. Early diagnosis was possible because of early x-ray examination and the recognition of the significance of air in the mediastinum. Definitive operation was possible in spite of the patient's condition, and closure of the esophagus was adequate, allowing him to take a diet from the third day on. The possible presence of a foreign body in the mediastinum, such as previously ingested food, is demonstrated by this patient, and may further strengthen the indication for early surgical intervention.

DISCUSSION

Spontaneous perforation of the presumably normal esophagus may not be as rare as the number of reported cases indicates. Since early diagnosis gives the best chance of satisfactory treatment, it is stressed that there is usually a characteristic symptomatology. One should always suspect this condition in any case in which severe pain in the lower chest or upper abdomen occurs during vomiting. Although there are no early characteristic physical signs, the finding of subcutaneous air in the neck in a patient with this story is diagnostic. However, even in the earliest stage after onset,

x-ray study of the chest will show air or fluid behind the heart in the mediastinum. This, together with the characteristic story, should be diagnostic. A swallow of radio-opaque oil with fluoroscopic observation can be used if further proof of the diagnosis is desired.

Although one of the patients discussed above, as well as 3 in the literature, survived on a conservative routine of therapy, such an outcome should not be anticipated in most cases. The majority of the patients in the cases reported in the literature were treated conservatively, without survival. Early definitive operation aimed at closing of the perforation, relief of the mechanical compression of the mediastinum, expansion of the lung and drainage of the pleural cavity should prove to be more successful. With modern technics of anesthesia and thoracic surgery, aided by the antibiotics, operation generally provides the most satisfactory form of treatment for these seriously ill patients.

SUMMARY

The clinical picture of spontaneous perforation of the normal esophagus is briefly reviewed, and reference to more complete studies is made.

The case histories of 3 patients successfully treated surgically are presented and discussed.

HYPERPARATHYROIDISM WITH NEPHROLITHIASIS*

Report of a Case with a Parathyroid Tumor Located Within the Thymus

M ABRAMS, MD,† A M RUTENBURG MD,‡ M F LESSES, MD,§ AND S L GARGILL, MD¶

BOSTON

THE existence of severe hyperparathyroidism without bone disease has been well established since it was first demonstrated in 1937 by Albright, Sulkowitch and Bloomberg.¹ The chief clinical manifestation of hyperparathyroidism in these patients consists of kidney stones or nephrocalcinosis, or both, without roentgenographic abnormalities of the bone or increased amounts of alkaline phosphatase in the blood. In the large series of cases of hyperparathyroidism studied by Albright and his co-workers,^{1,2} kidney disease was more common than bone disease. The incidence of renal calculi was likewise high in the Mayo Clinic series reported by Keating and Cook;³ unilateral or bilateral renal calculi being present in 18 of 24 cases of hyperparathyroidism, renal calculi or calcification of the kidneys was present in 92 per cent of their series. A subsequent report from the Mayo Clinic by Black⁴ has emphasized the significant increase in the proved diagnosis of parathyroid adenoma when hyperparathyroidism is carefully and regularly sought in patients with renal lithiasis. Norris,⁵ however, in a study of 322 reported cases of hyperparathyroidism found bone involvement alone in 59 per cent and renal lithiasis or renal calcification without bone involvement in only 5 per cent. This is a striking discrepancy, which Norris himself ascribed to insufficient appreciation of the inter-relation between nephrolithiasis and hyperparathyroidism in many of the earlier cases. In any event, it is agreed that the commonest complication of hyperparathyroidism is precipitation of calcium salts in the urinary tract. This results from the associated hypercalcemia with the formation of calcium phosphate stones in alkaline urine or calcium oxalate stones in acid urine. Renal calcification or nephrocalcinosis results from the deposition of calcium casts in the kidney tubules or in the renal parenchyma.

The case reported below is noteworthy because it illustrates the frequently encountered difficulties in diagnosis when bone disease is absent, mild but prolonged hyperparathyroidism with striking recurrence of renal and ureteral calculi without bone involvement, an unusual location of a mediastinal

parathyroid tumor, and the treatment of severe urinary sepsis complicating the nephrolithiasis by antibiotic and chemotherapeutic agents selected in accordance with *in vitro* sensitivity tests of the pathogenic organisms.

CASE REPORT

F W. (B I H 98960), an 18-year-old girl, first entered the Beth Israel Hospital on April 21, 1947, complaining of severe, colicky pain in the right flank of 48 hours' duration. Chills, fever (temperature of 104°F), nausea and vomiting were present during the same period. She had had two similar attacks 5 and 9 months previously in both of which the symptoms had persisted for 48 hours. The past history was otherwise uneventful.

Physical examination revealed a well developed, acutely ill girl. The skin was hot and dry. The pupils were equal and reacted well to light and accommodation, and the extraocular reactions were normal. There were no abnormalities of the fundi. Examination of the ears, nose and throat revealed no abnormalities. There were no palpable masses, lymph nodes, thrills or abnormal pulsations in the neck. The thyroid gland was not enlarged. The breasts were normal. There were no palpable axillary or inguinal lymph nodes. The lungs were normal to palpation, percussion and auscultation. The heart was not enlarged; the sounds were forceful; the rhythm was regular, and there were no murmurs. The abdomen was soft and flat, with marked tenderness over the right costovertebral angle; no masses or organs were palpable. The extremities showed no edema. The knee jerks and ankle jerks were equal and active. The plantar reflexes were normal.

The temperature was 104°F, the pulse 150, and the respirations 30; the blood pressure was 120/70.

The urine was grossly bloody and contained numerous white cells. Culture of the bladder urine revealed *Pseudomonas aeruginosa*, *Aerobacter aerogenes* and *Bacterium calcaligeres*. The serum calcium was 11.0, 11.1 and 11.7 mg per 100 cc during the 8-day period from April 28 to May 6 (Table 1). Intravenous and retrograde pyelograms demonstrated a large, obstructing calculus in the pelvis of the right kidney and three small calculi in the lower calyx of the left kidney.

On the 4th hospital day a right pyelonephrolithotomy was done, with removal of the calculus. Chemical analysis of the stone showed it to consist of calcium phosphate.

Streptomycin in a dosage of 2 gm daily, penicillin in a dosage of 500,000 units daily and sulfadiazine in a dosage of 2 gm daily during the postoperative period had no effect on the pyuria or bacilluria. The patient was discharged on May 28, symptom-free and afebrile but with the urine still containing *Escherichia coli* and *A. aerogenes*. No attempt to remove the stones in the left kidney was made. The significance of the slight hypercalcemia was not appreciated at this time.

On June 21 the patient was readmitted because of left-flank pain, chills, fever (temperature of 104°F), malaise, nausea and vomiting. She was acutely ill and markedly dehydrated. There was tenderness over the left costovertebral angle. Urinalysis revealed pyuria and bacilluria. Culture of the urine showed *Esch. coli* and *A. aerogenes*. After 4 days' treatment with 2 gm of streptomycin daily and 2 gm of sulfadiazine daily the patient became afebrile and symptom free; the urine, however, remained infected with the same organisms. She was discharged on the 11th hospital day.

Five days after discharge the patient was again readmitted because of chills, fever, left-costovertebral-angle pain, nausea

and vomiting. The temperature was 104.8°F, and the pulse 146. Retrograde pyelograms revealed two ureteral calculi in the region of the left ureterovesical junction and a larger stone in the left ureter at the level of the lower end of the sacrum. The lower ureteral calculi were removed by cystoscopic manipulation. Urine cultures at this time revealed *Esch coli*, *A. aerogenes* and *Ps. aeruginosa*. These organisms were resistant to streptomycin, penicillin, sulfadiazine and Mandelamine, both clinically and in vitro. The patient left

the hospital after 10 days, free of pain, but with an infected urine and a stone still present in the lower third of the left ureter. The bladder urine was sterile, but urine from the left nephrostomy showed *A. aerogenes*, *Esch coli* and *Ps. aeruginosa* on culture, although there was a marked decrease in the number of bacteria. The rapid formation of urinary calculi led to a search for hyperparathyroidism. Serum calcium determinations during the following 27 days showed values fluctuating between

*Cervical exploration performed on preceding day.

†Mediastinal operation (removal of parathyroid tumor) performed on preceding day.

a large obstructing calculus in the left renal pelvis and multiple smaller calculi in the lower calyx. A ureteral catheter could not be passed by the stone in the renal pelvis. The clinical course was characterized by recurrent chills and persistent fever, the temperature often reaching 105°F. A left pyelonephrolithotomy and nephrostomy were done on the morning after admission. The kidney was edematous, and its surface studded with small abscesses. The large stone in the pelvis was easily located and removed. The smaller calculi in the lower calyx were not removed because the pa-

12.7 and 8.6 mg per 100 cc (Table 2). The serum inorganic phosphorus levels ranged from 3.6 to 1.7 mg per 100 cc (Table 2). The Sulkowitch test, performed on urine obtained at 8-hour intervals each day for 14 days, varied from ++ to ++++ while the patient was on a low-calcium diet (0.22 gm of calcium per 2000 calories). Roentgenodiet (0.22 gm of calcium per 2000 calories) showed no decalcification or cyst formation. The calculus removed from the

*Dr. Fritz H. Schweinburg generously co-operated in the performance of the bacteriologic and in vitro sensitivity studies.

kidney was examined by Dr E L Prien, utilizing the method of optical crystallography, and found to consist of 95 per cent calcium phosphate⁶

In view of the recurrent nephrolithiasis, hypercalcemia and hypophosphatemia and the nature of the removed stone a diagnosis of hyperparathyroidism was made, and parathyroidectomy undertaken

The first operation consisted of a cervical exploration by Dr J Fine on April 2, 1948. Both thyroid lobes were fully exposed and examined without disclosure of any abnormalities. Exploration posterior to the trachea and esophagus and of all cervical tissues up to the hyoid bone and down to the jugular notch revealed no evidence of parathyroid tumor.

After this operation the abnormal values of serum calcium and inorganic phosphorus persisted (Table 2). The urinary infection was treated in succession with 5 gm of Mandelamine, 6 gm of sulfamethazine, 2 gm of sulfathiazole and 6 gm of sulfathaladine daily, with some clinical and bacteriologic improvement but without rendering the urine sterile. A second operation for the relief of the hyperparathyroidism was therefore undertaken on May 10 by Dr Fine. The anterior mediastinum was explored through a sternum-splitting incision. No parathyroid tumor was found in the plane anterior to the thymus. Accordingly, the thymus itself was dissected free from the underlying great veins. The lower pole of the left lobe was enlarged and on palpation contained a firm, discrete nodule about 5 mm in diameter buried in its substance. The thymus with its contained nodule was therefore removed. Examination of the nodule by frozen section showed it to consist of parathyroid tissue. Further exploration of the anterior mediastinum from the thoracic

FIGURE 1 Section Showing the Thymus at the Left and the Parathyroid Nodule at the Right. Note the acinar and tubular arrangement of the parathyroid cells and basal orientation of the nuclei ($\times 100$)

inlet to the top of the pericardium, anterior and posterior to the innominate veins and superior cava, disclosed no further evidence of parathyroid tissue.

On pathological examination the thymus was roughly triangular in shape and measured 3.5 cm in width, 3.5 cm in length and 0.4 cm. in thickness, and had the appearance of fibrofatty tissue. Near one of the angles a small nodular mass with the consistency of a lymph node was palpated. When dissected it had the shape and size of a small bean, measuring 4.5 by 4.0 by 5.5 mm. This was the same parathyroid nodule examined by frozen section at operation. Microscopical examination of the nodule showed a thin, incomplete fibrous-tissue capsule. No fat cells were enclosed in the section. The nodule was fairly vascular throughout. The epithelial cells comprising the nodule were present in bands and nests. There was a rich reticular and capillary

network, free of congestion. The bulk of the epithelial cells were very similar in appearance. In the smaller nests the peripheral cells in contact with the reticular stroma tended to become polarized. Occasionally, the polarized cells surrounded a lumen measuring 12 to 20 microns in diameter and containing in some areas deeply eosinophilic staining non-granular material. In many nests, particularly the larger ones, there was no tendency to polarization. The epithelial cells generally showed a thin but distinct cell wall, which was most obvious in the polarized cells. Their cytoplasm was quite uniform in appearance, finely granular, pale and acidophilic. The nuclei of the epithelial cells were round to oval and showed a fairly uniform size, measuring 10 to 15 microns. There was abundant chromatin arranged in a uniform, coarsely granular pattern in a nongranular, fainter basophilic background. About 10 per cent of the nuclei had

FIGURE 2 Section of Parathyroid "Tumor," Showing Moderate Variation in Cell Size and Density of Staining of the Nuclei ($\times 500$)

one or more nucleoli. No mitoses were seen. In occasional small areas the epithelial cells were larger with a paler, looser cytoplasm. The nuclei of these cells were larger and paler with more prominent nucleoli. These cells showed little polarization. They resembled but were not typical "wasserhelle" cells. Scattered through the sections were individual small clumps of "oxyphil" cells, which were more rounded and larger than the majority of the epithelial cells of the nodule. These cells had a more eosinophilic and slightly granular cytoplasm, with dark, round pyknotic nuclei (Fig 1 and 2).

After operation the patient received a high-calcium diet with dihydrotachysterol (A.T. 10) for 5 days to prevent tetany. The serum calcium on the 1st postoperative day was 8.3 mg per 100 cc of blood, and the serum inorganic phosphorus 3.3 mg per 100 cc of blood (Table 2). Serum calcium values during the subsequent 3-week period varied between 8.2 mg and 9.6 mg, and the serum phosphorus ranged between 3.3 and 3.8 mg per 100 cc. Clinically, the immediate postoperative course was uneventful, although the urine still remained infected.

As a result of the recurrent nephrolithiasis, surgical manipulation and persistent urinary infection, a complete stricture developed at the left ureteropelvic junction. Repeated dilatations over a 3-month period were unsuccessful in overcoming the obstruction. The patient continued to have attacks of chills and fever, although no new calculi were observed. Cultures of the urine from the right kidney and bladder showed many colonies of *Ps. aeruginosa* and *A. aerogenes*, whereas the cultures from the left nephrostomy tube showed *Ps. aeruginosa*, *Esch. coli*, *A. aerogenes*, *Streptococcus faecalis* and paracolon bacilli. These organisms were resistant to sulfanilamide, sulfathiazole, sulfadiazine, sulfamethazine, NU 445, penicillin and streptomycin in vitro.

However, all strains except *Ps aeruginosa* were very sensitive to aureomycin*.

Aureomycin in a dosage of 10 mg was given intramuscularly twice daily for 10 days without reaction except for pain at the site of injection. Twenty-four hours after the initiation of therapy with aureomycin, urine from the right kidney and bladder was found sterile by culture (Fig 3). Urine from the nephrostomy tube still produced a heavy growth of *Ps aeruginosa*. Irrigations of the left renal pelvis with

then 10 mg twice daily for the next 4 days, streptomycin in a dosage of 2.0 gm was also given daily. Urine from the right kidney and bladder became sterile in 24 hours and remained so throughout the hospital stay. The postoperative course was uneventful, the temperature returning to normal in 3 days. Four weeks postoperatively the patient was asymptomatic and free of urinary infection, as shown by a clear urine, which was free of abnormalities of the sediment or bacterial growth (Fig 4).

The patient was seen in the Out-Patient Department 4 months after removal of the parathyroid tumor. She was asymptomatic, and physical examination showed no abnormalities. The serum calcium was 8.2 mg, serum phosphorus 3.2 mg, total protein 6.8 gm, and ionized calcium 3.5 mg per 100 cc. The urine was sterile on culture and contained no abnormalities of the sediment. By January, 1949 (3 months after parathyroidectomy), she had gained 22 pounds in weight. A roentgenogram of the genitourinary tract at this time revealed no calculi. The urine was sterile on culture. The serum calcium measured 9.9 mg, serum phosphorus 3.4 mg, and total protein 6.7 gm per 100 cc, with an ionized calcium of 4.7 mg. The serum calcium 10 months after parathyroidectomy was 9.5 mg per 100 cc.

In this case of hyperparathyroidism, recurrent renal and ureteral calculi were complicated by severe bilateral urinary-tract infection. On the first admission a large obstructing calculus in the pelvis of the right kidney and three small calculi in the lower calyx of the left kidney were demonstrated, in association with marked pyuria and bacilluria. Serum calcium and phosphorus determinations revealed mild hypercalcemia and hypophosphatemia. The stone in the right kidney was removed surgically, but the stones in the left kidney were untouched. Streptomycin, penicillin and sulfadiazine had no effect on the urinary-tract infection. Two months after the first admission the patient was readmitted because of recurrent urinary sepsis. On this admission two ureteral calculi were removed from the lower end of the left ureter by cystoscopic manipulation. The organisms present in the urine were resistant to streptomycin, penicillin, sulfadiazine and Mandelamine both clinically and in vitro. The patient was discharged with an infected urine and a left ureteral stone. Seven months later she was readmitted with recurrent symptoms of urinary infection. A large obstructing calculus in the pelvis of the left kidney was surgically removed, but multiple smaller calculi in the lower calyx of the kidney were left. Optical crystallography of the removed calculus showed it to consist of calcium phosphate. Urine culture still revealed a marked pyuria and bacilluria. In vitro sensitivity tests showed NU 445 and sulfathiazole to be bactericidal to these organisms. These drugs temporarily cleared the urinary infection of the right kidney, but urine from the left nephrostomy continued to show a heavy growth of bacteria. At this point a clinical diagnosis of hyperparathyroidism was established by the finding of hypercalcemia and hypophosphatemia and hypercalcuria. A hyperfunctioning parathyroid tumor was discovered, after a negative exploration of the neck, in the substance of the thymus gland

FIGURE 3 Effect of Aureomycin before Nephrectomy

aureomycin (1 mg in 10 cc of physiologic saline solution) through the nephrostomy were not bactericidal. After termination of therapy, urine from the right kidney and bladder continued to be sterile. Urine from the left kidney, however, showed a moderate growth of *Ps aeruginosa*.

Two weeks later the patient again experienced pain in the left flank associated with chills, fever (temperature of 103°F), nausea and vomiting. The infection again involved both

FIGURE 4 Effect of Aureomycin after Nephrectomy

kidneys and bladder, and there were positive cultures of *Ps aeruginosa* and *Esch coli* in the urine.

Because of the persistent urinary-tract infection and the multiple calculi in the lower calyx of the left kidney, an attempt was made to correct the obstruction at the uretero-pelvic junction. At operation the severe inflammatory reaction, dense adhesions and an intrarenal location of the pelvis rendered plastic procedures impossible so that a nephrectomy was performed.

After nephrectomy, the patient received 20 mg of aureomycin intramuscularly twice daily for the first 3 days, and

*This antibiotic was supplied by the Lederle Laboratories Division of the American Cyanamid Company, New York City.

†The strain of *Ps aeruginosa* isolated from the bladder was resistant in vitro to streptomycin.

The serum calcium returned to normal on the first postoperative day and subsequently remained normal.

During all hospital admissions the urinary infection proved resistant *in vitro* and clinically to penicillin, streptomycin, sulfadiazine, sulfamethazine and Mandelamine NU 445 and sulfathiazole had a transitory beneficial effect. Aureomycin⁹ quickly cleared the infection of the right kidney and bladder (Fig 3). However, the left kidney, because of an impassable stricture at the ureteropelvic junction and the presence of calculi remained infected and caused severe clinical symptoms until removed.

DISCUSSION

Although the number of reported cases of hyperfunctioning parathyroid adenoma now numbers almost 400 and the essential features of the syndrome have been well described, the present case illustrates the difficulties of achieving diagnosis and cure when the tumor is small, obscurely located and associated with minimal hyperfunction.

Albright and Reifenstein² have pointed out that hyperparathyroidism may exist in 4 clinical forms, tabularly represented as follows:

	BONE DISEASE	KIDNEY DISEASE
(A)	Present	Absent
(B)	Present	Present
(C)	Absent	Present
(D)	Absent	Absent

Hyperparathyroidism without bone or kidney disease has been reported but once, in this form diagnosis must initially depend upon characteristic blood chemical findings and clinically could only be suspected from the symptom of polyuria. The other forms of hyperparathyroidism are common and offer diagnostic clues either in the presence of bone disease such as osteitis fibrosa cystica or kidney disease as nephrolithiasis or, more rarely, as renal calcification.

The starting point in the diagnosis of hyperparathyroidism is a problem in quantitative chemistry. One must know the precise range of normal values for the method utilized in the hospital laboratory. If the total protein level is normal, serum calcium values above 11 mg per 100 cc must be regarded as suspect when associated with nephrolithiasis, osteoporosis, osteitis fibrosa cystica or unexplained polyuria. If there is simultaneous depression of the serum phosphorus level the diagnosis becomes increasingly certain.

It is clear that there is little diagnostic problem in cases in which the serum calcium is above 12 mg with characteristic bone changes. Difficulties arise, however, in cases like the present, in which bone changes were completely absent and the serum calcium persistently hovered about 11 mg per 100 cc, occasionally dropping to completely normal values (Table 2) or occasionally rising to slightly

abnormal values. In these situations the use of the Sulkowitch test as an index of calcuria is important, since the demonstration of a high-calcium output in the urine, with normal or slightly elevated serum calcium, should lead to further search for hyperparathyroidism. Several factors influence the interpretation of the Sulkowitch test, especially the previous diet, the concentration of the urine, the age of the patient and the presence or absence of renal disease. For this reason serial tests are most informative, the simplicity of the test lending itself readily to this purpose.

The degree of elevation of the serum calcium and consequently the degree of depression of the serum phosphorus is roughly proportional to the size of the tumor¹⁰ except in larger adenomas, when the proportionality is less. The smallness of the tumor in the present case was entirely consistent with the minimal elevations of the serum calcium observed at the first and fourth admissions. The tumor size, however, does not explain the sudden decline of the calcium values to normal or subnormal values during the fourth admission (Table 2) for a period of six days, followed by a return to slight hypercalcemia. An increased phosphate intake in the diet could explain such a decrease but would be accompanied by an elevation of the serum phosphorus level. Since this did not occur the explanation is more likely to be found in the intravenous infusion of saline solutions, which were given during this period because of the patient's condition. Physiologic saline solution, according to Albright and Reifenstein,² is a useful agent in parathyroid poisoning, presumably through a temporary effect in lowering the blood calcium.

Although small tumors do not elevate the blood calcium very much, this minimal elevation is entirely adequate for the production of nephrolithiasis in the severe form exhibited by this patient with both multiple stones, a rapid rate of stone formation and severely damaging renal infection.

Whereas the reported figures of parathyroid adenomas that are completely mediastinal have varied from 7 to 17 per cent,^{4, 5, 11} the number that are completely intrathymic is extremely small. Cope¹¹ has reported only 3 such tumors in his large series, whereas Norris,⁵ in his collective review of 322 cases, mentions 9. Embryologically, the intrathymic location is readily explicable because the lower parathyroid glands develop in close proximity to the thymus gland, descending partially with it but usually dropping off opposite the lower pole of the thyroid gland. Occasionally, however, the parathyroid glands grow down into the mediastinum adjacent to or within the body of the thymus gland.

The nature of the parathyroid lesion in this case was clearly that of a hyperfunctioning tumor or adenoma, since removal of a single, encapsulated nodule resulted in rapid and permanent disappearance of the signs and symptoms of hyperpara-

thyroidism Hyperparathyroidism resulting from primary hyperplasia always involves all four parathyroid glands and therefore will not remit with removal of a single gland

The early diagnosis of hyperparathyroidism is particularly important because the nephrolithiasis or nephrocalcinosis frequently associated with the disease may lead to irreparable kidney damage or prolonged renal infection with loss of a kidney, as illustrated by the case reported above Chemotherapy based on in vitro sensitivity tests, combined with relief of obstruction and removal of an infected kidney, led to eventual clearing of the sepsis of the genitourinary tract

SUMMARY

A case of hyperparathyroidism with nephrolithiasis and without bone disease caused by a small intrathyroidic parathyroid tumor is reported Complete clinical cure of the hyperparathyroidism followed removal of the parathyroid lesion

The difficulties in the clinical diagnosis are discussed

Genitourinary sepsis of severe degree was the chief complication This sepsis was eventually con-

trolled by nephrectomy and the selection of appropriate antibiotics on the basis of in vitro sensitivity tests

CONDITIONED-REFLEX TREATMENT OF ALCOHOLISM

II. The Risks of Its Application, Its Indications, Contraindications and Psychotherapeutic Aspects

JOSEPH THIMANN, M.D.*

BOSTON

IN THE first article about the conditioned-reflex therapy its rationale and technic were discussed¹ The purpose of the present study is to show the risks, indications, contraindications, efficacy and psychotherapeutic aspects

To establish a reflex association between alcoholic beverages and vomiting, emetine hydrochloride is used as the unconditioned stimulus The pharmacologic interest in emetine started with its use for treatment of amebic dysentery, liver abscesses and alveolar pyorrhea

Emetine is one of the alkaloids of ipecacuanha Its pharmacologic properties were the object of extensive studies during the greater part of the nineteenth century However, not until 1893 did Paul and Cownley² demonstrate that the so-called emetine of previous workers was in reality a mixture of two alkaloids, emetine and another one, which they called "cephaeline"

Two years later, the pure emetine was for the first time investigated by Wild,³ who studied its emetic and other properties He found that it lowered the blood pressure and in excessive doses caused an arrest of the heart in diastole

The mode of excretion of emetine could not be determined No traces were found in gastric or intestinal contents or in the urine Baermann and Heinemann⁴ have stated that "with moderate sized doses of 60 to 150 mg there are no symptoms"

If 120 to 150 mg are given in daily repeated injections, there appear, after three or four injections, malaise, lassitude, slight vertigo and loss of appetite These symptoms disappear in from 24 to 72 hours after the emetine has been discontinued

Vedder⁵ called attention to the fact that rabbits died after small intravenous doses of emetine and advised strongly against the intravenous application in human beings

Other investigators described the gastrointestinal side effects such as nausea, vomiting and diarrhea

Levy and Rowntree⁶ cited several observers with 20 case histories One of these patients received a total dosage of 1.45 gm (24 gr.), another 1.28 gm (21 gr.), and a third 1.75 gm (29 gr.) The first 2 patients recovered although not without a transitory phase of diarrhea and a mild peripheral neuritis

A recent paper by Dack and Moloshok⁷ cited Heilig and Visveswar, who "failed to observe any significant alteration in the EKG, blood pressure

*Medical director, Washingtonian Hospital.

or orthodiagram of 14 patients treated with twelve intramuscular injections of 1 grain (0.06 gm) of emetine hydrochloride daily." Hardgrove and Smith, cited in the same paper, observed in a series of 72 patients only 1 serious cardiac effect. They concluded that emetine hydrochloride in therapeutic doses produced only minor and transient electrocardiographic changes and that there was little risk involved in the use of emetine hydrochloride if electrocardiograms were taken during the course of treatment and the patient was kept in bed.

Dack and Moloshok discussed further their own observations of 9 patients, who were treated for amebic dysentery with emetine hydrochloride. The total dose ranged from 0.45 to 1.42 gm (7 to 22 gr). The neuromuscular manifestations of toxicity such as general muscular aching and weakness, tremor of the hands and dizziness usually appeared during the period of administration of emetine hydrochloride. In 8 of these cases, however, an abnormal electrocardiogram was not demonstrated until two to twenty-one days after the last injection of emetine.

The clinical examination of the cardiovascular system in these 9 cases did not show strikingly abnormal findings. Three patients displayed moderate tachycardia at rest and after mild effort. In 1 patient it was associated with presystolic gallop rhythm. Another patient complained of a mild precordial discomfort. In 5 cases there was dyspnea and fatigue of various degrees on exertion. None of the patients showed any abnormality in the size or configuration of the heart by x-ray examination. There was no significant lowering of the blood pressure.

In 3 cases diarrhea occurred during the course of treatment. The symptoms disappeared spontaneously when the use of emetine was discontinued.

The authors recommend absolute rest in bed during the course of treatment, daily recordings of the pulse rate at frequent intervals (tachycardia may be the first clinical sign of toxic effect), the patient should be examined and questioned at least daily for diarrhea, fatigue, dyspnea on exertion, muscular tremors or weakness and dizziness, an electrocardiogram should be taken before the treatment is instituted, after the fifth grain, at the completion of the course of the treatment and one week later (use of the drug should be discontinued if significant changes are found), emetine should not be used in the presence of organic heart disease and should be used with great caution in patients who are anemic and debilitated.

It may be recalled that the first report about the use of emetine for treatment of alcohol addiction was presented by Voegtlin⁸ in 1940.

Less than two years later the conditioned-reflex therapy by means of emetine was started for the first time on the eastern seaboard at the Wash-

ingtonian Hospital in Boston, 282 patients have been treated to date.* Their ages ranged from seventeen to sixty-four years. The total dose of emetine hydrochloride, as injected subcutaneously, during the initial series of six to seven daily sessions, varied from 0.5 gm (7.5 gr) to 0.85 gm (13¼ gr). Lately, it has been found that a series consisting of six sessions suffices to establish the reflex. This reduced the total dose to 0.675 gm (11¼ gr). As mentioned in the previous article¹ the patient receives prior to the injection a capsule containing 60 to 150 mg (1 to 2½ gr) of additional emetine hydrochloride by mouth with 1 to 3 glasses of water. It is assumed that very little of this additional emetine is absorbed because, after the dissolution of the capsule, the emetine becomes dissolved or suspended in the water contained in the stomach, most of which is vomited as soon as the emesis begins.

All but a few of the 282 patients treated reacted after two to four injections with diarrhea, mostly of a mild degree (two to five bowel movements daily). Only nine patients (3.19 per cent) claimed ten to fifteen bowel movements daily. Discontinuance of emetine injections for one to several days, combined with generous doses of kapectate, stopped the diarrhea. The initial series was continued, if necessary, with additional intermissions. Ten patients complained of cramping pain of the intestines or genitals, but only during the treatment sessions, when the emetine (and pilocarpine?) action was at its peak. The end of the treatment session, sometimes with the aid of a hot-water bottle, terminated the spasms.

Other side effects of emetine application were the neuromuscular disturbances. Ten to fourteen days after the initial series approximately 60 per cent of all patients treated displayed general muscular weakness and aching, especially in the lower extremities. The degree of these neuromuscular manifestations was light to moderate. The patients were able to walk and to climb and descend stairs without too much inconvenience. In only 2 cases (0.7 per cent) — both female patients, incidentally — the degree of the neuromuscular involvement was such that the patients were, for two or three weeks, able to walk on level ground only. All these neuromuscular manifestations, however, were safely overcome, at the latest, after several weeks of convalescence. Thus, all the side effects described above were mild.

Only 5 patients out of 282 treated with emetine (1.43 per cent) reacted with cardiovascular manifestations of any degree of severity.

One of these patients was a thirty-year-old, husky man. His electrocardiogram was described by the cardiologist as indicating a moderate degree of myocardial fibrosis — not extensive enough to

*This figure includes female patients who had to be treated outside the Washingtonian Hospital because of the lack of facilities for such patients.

CONDITIONED-REFLEX TREATMENT OF ALCOHOLISM

II. The Risks of Its Application, Its Indications, Contraindications and Psychotherapeutic Aspects

JOSEPH THIMANN, M D *

BOSTON

IN THE first article about the conditioned-reflex therapy its rationale and technic were discussed¹ The purpose of the present study is to show the risks, indications, contraindications, efficacy and psychotherapeutic aspects

To establish a reflex association between alcoholic beverages and vomiting, emetine hydrochloride is used as the unconditioned stimulus The pharmacologic interest in emetine started with its use for treatment of amebic dysentery, liver abscesses and alveolar pyorrhea

Emetine is one of the alkaloids of ipecacuanha Its pharmacologic properties were the object of extensive studies during the greater part of the nineteenth century However, not until 1893 did Paul and Cownley² demonstrate that the so-called emetine of previous workers was in reality a mixture of two alkaloids, emetine and another one, which they called "cephaeline"

Two years later, the pure emetine was for the first time investigated by Wild,³ who studied its emetic and other properties He found that it lowered the blood pressure and in excessive doses caused an arrest of the heart in diastole

The mode of excretion of emetine could not be determined No traces were found in gastric or intestinal contents or in the urine Baermann and Heinemann⁴ have stated that "with moderate sized doses of 60 to 150 mg there are no symptoms"

If 120 to 150 mg are given in daily repeated injections, there appear, after three or four injections, malaise, lassitude, slight vertigo and loss of appetite These symptoms disappear in from 24 to 72 hours after the emetine has been discontinued

Vedder⁵ called attention to the fact that rabbits died after small intravenous doses of emetine and advised strongly against the intravenous application in human beings

Other investigators described the gastrointestinal side effects such as nausea, vomiting and diarrhea

Levy and Rowntree⁶ cited several observers with 20 case histories One of these patients received a total dosage of 1 45 gm (24 gr), another 1 28 gm (21 gr), and a third 1 75 gm (29 gr) The first 2 patients recovered although not without a transitory phase of diarrhea and a mild peripheral neuritis

*Medical director, Washingtonian Hospital

individual psychotherapy After several failures to prevent relapses, his therapist referred him for conditioned-reflex therapy When the patient completed his initial series of the conditioned-reflex therapy, he was advised to return four weeks later for his first reinforcement Circumstances delayed his return by an additional three months As it happened he was able to abstain from drinking for those four months, but when he again, for external reasons, postponed his second reinforcement he relapsed He then accepted the suggestion of a full retreatment, and six years later was able to report that he was apparently completely cured

Intrinsic reasons for relapse observed in these patients include an ambivalent attitude regarding abstinence, poor rapport with the therapist (father hostility) and subsequent rejection of follow-up psychotherapy and neurotic difficulties in facing life without the crutch — alcohol Such recidivists have naturally a poor prognosis

The indications for the conditioned-reflex therapy may be conceived in a twofold way From a narrow point of view, it seems plausible to state that it should be given to patients with whom other therapeutic approaches have failed However, in view of the unusually high success of the conditioned-reflex therapy, as compared with other kinds of therapy, a broader conception is justified — that is, all patients who are physically and psychologically eligible should actually have the opportunity to avail themselves of it The latter point of view will be even more acceptable if the working hypothesis of the autonomous, self-perpetuating, abnormal reflex of addictive drinking is kept in mind The contraindications, which have been listed elsewhere,¹⁰ are briefly as follows I Q markedly below 100, constitutional psychopathy, lack of intellectual or emotional ability to recognize the necessity of permanent abstinence, record of serious criminal offenses committed in a state of sobriety, combination of alcohol and drug addiction, and acute psychosis

Physical contraindications include disturbances of the cardiovascular-renal system, active tuberculosis of the lungs, active peptic ulcer and cirrhosis of the liver

EFFICACY

The efficacy of the treatment is demonstrated by the following statistics 282 patients have undergone the conditioned-reflex therapy since February, 1942, and 7 of these did not finish the initial series, the total thus being reduced to 275 Results have been verified, in most cases, by periodic, personal contacts in the form of weekly interviews, reinforcements, semimonthly abstinence-club meetings and, for patients living in remote parts of the United States and Canada, by correspondence, which is rechecked by social workers, local physicians, probation officers and relatives

Out of these 275 patients no follow-up information is available on about 30 patients, leaving a remainder of 245 Of these, 125 are still total abstainers This figure includes 9 who relapsed once and had to be retreated Of the 125 patients, 21 have been totally abstinent for six to seven years, 37 have been abstinent for five to six years, and 15 for four to five years The rest have been abstinent from one to three years

The over-all percentage of abstainers among the 245 patients is 51.02 These statistics purposely do not exclude patients who combined alcohol with drug addiction, patients who accepted the treatment not quite voluntarily, but under certain pressure from employers or their families, and patients whose chance for rehabilitation was impaired by factors beyond those stemming from alcohol addiction, such as poor working history, lack of trade or profession, criminal background or an occupation that exposes them continuously to alcoholic beverages, such as package-store owners, bartenders, butlers and businessmen who have to entertain

PSYCHOTHERAPEUTIC ASPECTS AND MECHANISMS

To consider the conditioned-reflex treatment a mere physiologic or drug therapy would be tantamount to considering only one of its aspects Like any other physiologic or drug therapy, only even more so, the conditioned-reflex therapy includes a considerable amount of dynamic psychotherapy As pointed out elsewhere¹⁰ and in the opinion of other authors,* alcoholic patients often suffer from feelings of guilt and inferiority The patient undergoing the conditioning against alcohol perceives the repeated exposure to the repulsive sight, smell and taste of alcoholic beverages with subsequent nausea as punishment and purification This procedure of atoning reduces and eliminates his feelings of guilt On a more superficial level the patients experience a feeling of heroic accomplishment This in itself is an excellent counterweight for their feelings of diffidence and inadequacy with all the subsequent self-criticism and self-hatred Thus, it seems reasonable to consider the conditioned-reflex therapy as a psychosomatic approach to a truly psychosomatic disease

SUMMARY AND CONCLUSIONS

The rationale, technic, risks, indications, contraindications, efficacy and psychotherapeutic aspects of the conditioned-reflex treatment as applied to 282 patients are discussed

A new conception of the autonomous character of alcohol addiction in relation to the underlying neurosis is offered Psychotherapeutic mechanisms involved in the conditioned reflex therapy are pointed out

*Bird¹¹ states "The alcoholic who always feels terribly guilty whether he admits it or not, often feels a need to be punished and being punished may lessen his guilt"

represent a contraindication for conditioned-reflex therapy. The initial series of the treatment involved seven injections with a total dose of 0.54 gm (9 gr) of injected emetine, followed by an additional injection of 0.15 gm ($2\frac{1}{2}$ gr) of injected emetine nine days later. During that whole period this patient did not display any tachycardia, drop in blood pressure, arrhythmia, gastrointestinal or neuromuscular side effects. Fifteen days after the initial series, the patient traveled to a neighboring state for some urgent business. For two days, he was exposed to relatively marked physical strain. Three days later he complained of weakness of the lower extremities, shortness of breath and occasional precordial distress. An electrocardiogram and clinical examination revealed sinus tachycardia. Five days later he was definitely better. His pulse was still 140, but the blood pressure rose to 110 systolic, 80 diastolic. Another five days later, the pulse slowed down to 110, eight days later it was 96, and the blood pressure was 125 systolic, 70 diastolic. Although the electrocardiogram still showed abnormalities, it also revealed progressive improvement in the condition of the myocardium. There was still gallop rhythm. From then on the blood pressure remained normal. The only abnormal sign—the gallop rhythm—disappeared finally three weeks later.

Another patient, an asthenic, fifty-year-old man with an asthmatic bronchitis and a positive blood Hinton reaction, felt, thirteen days after a total dose of 0.8 gm (13 gr), dizzy and lightheaded for one day. Aside from this side effect, he complained of muscular weakness and aching for twenty-three days.

Several hours after the first emetine injection of 55 mg a third patient, a slender, run-down, fifty-seven-year-old man, showed severe gastrointestinal and circulatory manifestations, such as severe, watery diarrhea, pallor, a very small, rapid pulse (120 per minute), cramps in both legs and cold extremities. Fifteen minutes after caffeine injection he felt more comfortable, and the pulse was 96 and better filled. The blood pressure was 120 systolic, 80 diastolic. The rest of the series of injections was well tolerated and provoked no immediate untoward reactions. However, a week after the end of the series, the patient complained of fainting spells and palpitations, shortness of breath, tachycardia and muscular weakness. An electrocardiogram showed auricular fibrillation. Rest in bed, digitalis and ammonium chloride brought the heart back to normalcy. From then on the patient was able to tolerate the additional reinforcements without any toxic manifestations.

Sometimes lack of judgment and restlessness, not at all a rare phenomenon in alcoholic patients, may prevent a patient in need of rest in bed from following medical advice. Such nonco-operation

may prove fatal, as the following case history illustrates.

A 35-year-old unusually obese man (weighing 241 lb), with a blood pressure of 106/76, negative liver tests and an electrocardiogram within normal limits, underwent the initial series of the conditioned-reflex treatment after recovery from a bout of drinking lasting 6 weeks. The total dose of injected emetine was 0.77 gm ($12\frac{3}{4}$ gr). He claimed that he was too restless to stay in bed during the days of the initial series and was even more restless after that. He insisted upon leaving the hospital only 2 days after completing the initial series and on resuming his occupation as a very active salesman.

One week after discharge from the hospital, tachycardia and gallop rhythm developed. Again, he refused hospitalization, for business reasons, for another 2 days. Finally, he returned to the hospital with complaints of general weakness and shortness of breath. Physical examination revealed a heart enlarged in all diameters, with the apical beat in the sixth interspace, the heart rate was 110 and regular, and the blood pressure 110/80. From then on the cardiac failure progressed rapidly. Approximately 12 hours after readmission the patient died.

Kattwinkel⁹ has recently reported an additional fatal case. Fortunately, such a fatal termination occurred in only 2 cases out of 282 treated, representing a mortality of 0.7 per cent.

To reduce to a minimum and, if possible to eliminate the risks of toxic manifestations altogether, three modifications are now applied. In the first place the initial series of injections consists now of only six, the total initial dose of injected emetine thus being reduced to 0.675 gm ($11\frac{1}{4}$ gr). Secondly, pilocarpine has been eliminated from the injectable emetine solution. Thirdly, the conditioned reflex therapy is applied only to patients who accept the plan of rest in bed and hospitalization for an additional four weeks after completing the initial series of treatments. The number of patients who have complied with this stipulation is so far too small to form a basis for conclusions. It has been reassuring, however, that no cardiovascular side effects have developed.

The primary research plan at the Washingtonian Hospital is either to modify emetine chemically or to substitute for it another suitable emetic, with the goal of preventing not only the cardiovascular complications but also the side effects.

A discussion of the efficacy of the conditioned-reflex therapy would be incomplete without mention of the question of recidivism. The relapse seems to be caused in some cases by external and in others by intrinsic factors. The first group may be benefited either by single reinforcements or by a full retreatment including the initial series. The prognosis for such patients is good, probably because of the very fact that it takes considerable maturity and determination to return for additional treatment.

One patient who relapsed largely for external reasons was a man in his forties, in a responsible position, who clearly realized the necessity for total abstinence from alcoholic beverages and who did his best to obtain it by undergoing a course of in-

dividual psychotherapy. After several failures to prevent relapses, his therapist referred him for conditioned-reflex therapy. When the patient completed his initial series of the conditioned-reflex therapy, he was advised to return four weeks later for his first reinforcement. Circumstances delayed his return by an additional three months. As it happened he was able to abstain from drinking for those four months, but when he again, for external reasons, postponed his second reinforcement he relapsed. He then accepted the suggestion of a full retreatment, and six years later was able to report that he was apparently completely cured.

Intrinsic reasons for relapse observed in these patients include an ambivalent attitude regarding abstinence, poor rapport with the therapist (father hostility) and subsequent rejection of follow-up psychotherapy and neurotic difficulties in facing life without the crutch — alcohol. Such recidivists have naturally a poor prognosis.

The indications for the conditioned-reflex therapy may be conceived in a twofold way. From a narrow point of view, it seems plausible to state that it should be given to patients with whom other therapeutic approaches have failed. However, in view of the unusually high success of the conditioned-reflex therapy, as compared with other kinds of therapy, a broader conception is justified — that is, all patients who are physically and psychologically eligible should actually have the opportunity to avail themselves of it. The latter point of view will be even more acceptable if the working hypothesis of the autonomous, self-perpetuating, abnormal reflex of addictive drinking is kept in mind. The contraindications, which have been listed elsewhere,¹⁰ are briefly as follows: I Q markedly below 100, constitutional psychopathy, lack of intellectual or emotional ability to recognize the necessity of permanent abstinence, record of serious criminal offenses committed in a state of sobriety, combination of alcohol and drug addiction, and acute psychosis.

Physical contraindications include disturbances of the cardiovascular-renal system, active tuberculosis of the lungs, active peptic ulcer and cirrhosis of the liver.

EFFICACY

The efficacy of the treatment is demonstrated by the following statistics. 282 patients have undergone the conditioned-reflex therapy since February, 1942, and 7 of these did not finish the initial series, the total thus being reduced to 275. Results have been verified, in most cases, by periodic, personal contacts in the form of weekly interviews, reinforcements, semimonthly abstinence-club meetings and, for patients living in remote parts of the United States and Canada, by correspondence, which is rechecked by social workers, local physicians, probation officers and relatives.

Out of these 275 patients no follow-up information is available on about 30 patients, leaving a remainder of 245. Of these, 125 are still total abstainers. This figure includes 9 who relapsed once and had to be retreated. Of the 125 patients, 21 have been totally abstinent for six to seven years, 37 have been abstinent for five to six years, and 15 for four to five years. The rest have been abstinent from one to three years.

The over-all percentage of abstainers among the 245 patients is 51.02. These statistics purposely do not exclude patients who combined alcohol with drug addiction, patients who accepted the treatment not quite voluntarily, but under certain pressure from employers or their families, and patients whose chance for rehabilitation was impaired by factors beyond those stemming from alcohol addiction, such as poor working history, lack of trade or profession, criminal background or an occupation that exposes them continuously to alcoholic beverages, such as package-store owners, bartenders, butlers and businessmen who have to entertain.

PSYCHOTHERAPEUTIC ASPECTS AND MECHANISMS

To consider the conditioned-reflex treatment a mere physiologic or drug therapy would be tantamount to considering only one of its aspects. Like any other physiologic or drug therapy, only even more so, the conditioned-reflex therapy includes a considerable amount of dynamic psychotherapy. As pointed out elsewhere¹⁰ and in the opinion of other authors,* alcoholic patients often suffer from feelings of guilt and inferiority. The patient undergoing the conditioning against alcohol perceives the repeated exposure to the repulsive sight, smell and taste of alcoholic beverages with subsequent nausea as punishment and purification. This procedure of atoning reduces and eliminates his feelings of guilt. On a more superficial level the patients experience a feeling of heroic accomplishment. This in itself is an excellent counterweight for their feelings of diffidence and inadequacy with all the subsequent self-criticism and self-hatred. Thus, it seems reasonable to consider the conditioned-reflex therapy as a psychosomatic approach to a truly psychosomatic disease.

SUMMARY AND CONCLUSIONS

The rationale, technic, risks, indications, contraindications, efficacy and psychotherapeutic aspects of the conditioned-reflex treatment as applied to 282 patients are discussed.

A new conception of the autonomous character of alcohol addiction in relation to the underlying neurosis is offered. Psychotherapeutic mechanisms involved in the conditioned reflex therapy are pointed out.

*Bird¹¹ states: "The alcoholic who always feels terribly guilty whether he admits it or not, often feels a need to be punished and being punished may lessen his guilt."

The therapeutic efficiency of the method available at the Washingtonian Hospital, the only American hospital specializing in the treatment of alcohol addiction, is considered very encouraging

THE MANAGEMENT OF ABNORMAL UTERINE BLEEDING*

GEORGE VAN S SMITH, MD †

BROOKLINE, MASSACHUSETTS

EXCEPT for the stain of newborn females and the normal menstruation of constitutional precocity, all the rare cases of uterine bleeding during the period of childhood and preadolescence are but one manifestation of the precocious puberty associated with the following unusual conditions: certain cases of midbrain damage, Albright's disease, exceptional cases of tumor of the adrenal cortex, granulosa-cell tumor of the ovary and, very exceptionally, chorioncarcinomatous teratoma of the ovary. The observation of premature growth and development, then, is the signal for immediate investigation and possible operation. Uterine bleeding after the establishment of the menopause is due most often to intrauterine or ovarian neoplasms, or both, rarely to cancer or sarcoma in the myometrium or to tubal cancer and very rarely to intrinsic vascular disease in the uterus. Between the menarche and the menopause the definite causes of abnormal uterine bleeding are intrauterine tumors and infections, pathologic pregnancy, both intrauterine and extrauterine, retained products of gestation, submucous fibroids, some estrogenic tumors of the ovary, diseases impairing the ability of the circulating blood to clot, and ovarian dysfunction. Placental dysfunction is, of course, involved in the bleeding of pathologic pregnancy. Less clear-cut causes during this span of life are myometrial and subserous tumors, pelvic inflammations, endometriosis, retroversion of the uterus, nonestrogenic tumors of the ovary and uterine fibrosis, since these entities are often present without any abnormality of flow.

It is quite apparent that all the conditions listed — and the list is essentially complete — are, with the exception of infections, not the primary causes of

abnormal uterine bleeding. Nor are they the ultimate causes. They are intermediate causes whose primary etiologies are still unknown. As a result of the action of one or more of these intermediate causes, the ultimate factors, chemical and mechanical, that actually rupture blood vessels within the uterus come into play in an abnormal way.

MANAGEMENT

According to the indications of present knowledge most, if not all, of the complications of pregnancy and the uterine bleedings that sooner or later accompany them are due to placental dysfunction. Because of ignorance concerning primary etiologies, the assumption has been made for years that any disease or disorder anywhere in the body may somehow lead to placental dysfunction. The improvements from better prenatal study and care have justified this assumption. Also because of ignorance concerning specific primary etiologies, it is assumed that any disease or disorder may be an etiologic factor and as such may make ovarian dysfunction a cause of abnormal flowing in the nonpregnant woman, in addition to, or in the absence of, any of the causes listed above. This is the reason for including in the long-range management of abnormal uterine bleeding the study and treatment of the whole patient, even though the beneficial effects may not become at once apparent. Especial and immediate attention is, of course, directed not only to the uterus and adnexa but also to the vulva, vestibule, urethra, vagina and cervix for sources of bleeding. Some women are, understandably, still averse to being examined while flowing. Tragic delays too often result. Their objection is easily overcome when the dangers of delaying the diagnosis and prescribing medication without a diagnosis are explained.

Since it would be futile in a presentation of this sort to attempt a discussion of pathological physiol-

*Presented at the annual meeting of the Massachusetts Medical Society, Worcester, Massachusetts, May 26, 1949.

ogy, diagnosis and treatment in relation to all the conditions concerned in abnormal uterine bleeding, a few points under the headings of surgery, radiation and the use of hormones are considered

Surgery

During the early teens operation is practically never necessary, in either the diagnosis or the treatment of this complaint, which is usually due to ovarian dysfunction of undeterminable cause and responds to the progesterone therapy described below. Some of these young women will have recurrent ovarian dysfunction that can be controlled by progesterone and finally ceases developing. Occasionally, however, one of them continues to have recurrent dysfunctional flowing, and cancer of the endometrium will be found during the twenties or early thirties. Drs Arthur T Hertig and Sheldon C Sommers will soon report 16 such patients whose endometrial hyperplasia became malignant. The patient with persistently recurring dysfunctional bleeding, then, requires particular attention in the matter of follow-up study and endometrial biopsy.

From the age of eighteen on, surgical diagnostic and therapeutic procedures are, of course, increasingly indicated for a great variety of situations of which abnormal uterine bleeding is a sign. This brings me to an aspect of conservative pelvic surgery concerning which I have a strong conviction. All gynecologists have the relatively frequent experience of seeing patients with this complaint who have had previous operations consisting of the excision of both tubes or bilateral tubal ligation, with or without ovarian surgery. These women are usually over thirty-five years old. A uterus capable of only one function, menstruation, yet still capable of being the source of serious or very serious trouble has been conserved. At the Free Hospital for Women 35 patients with cancer of the cervix and 6 with endometrial cancer have had these operations. In addition, 60 to 100 women with bleeding associated with fibroids, chronic pelvic inflammation, polyps and ovarian-endometrial dysfunction who have had these operations are treated each year. The operations had been performed with the mistaken idea, which was due to earlier teachings, that menstruation must be important for health, even in the absence of the ability to conceive. There is no evidence, however, that menstruation has any physiologic value except in relation to fertility. On the contrary, there is ample evidence of its being indeed "the curse." My own conclusion from available knowledge is that it is an expression in the non-pregnant woman of a process that must be very important in the physiology of pregnancy. This process is decidual necrosis, which, according to Dr Hertig, is a constant feature of human gestation. And certainly amenorrhea in itself is in no way ever harmful. Therefore, it is my firm conviction, and I submit it for serious consideration, that when opera-

tions involving sterilization are required, the continued health of these patients is more certainly assured by the removal of the uterus. This prophylaxis eliminates not only menstruation with all its attendant unpleasantness, including premenstrual tension, which is so common to all ages, especially after thirty-five, but also the potential source of tumors, benign and malignant. In retrospect it would have been life saving for many women. It almost completely eliminates soreness of the breasts, and fibrocystic changes in the breasts may disappear after it. I am advocating hysterectomy only in this limited group of patients and not the removal of any ovarian tissue except as indicated in the individual case. When normal ovaries are conserved, menopausal symptoms do not occur prematurely. There are only three exceptions to my proposal. One is that some women, though none in my experience, consider uterine bleeding an indispensable manifestation of their femininity. Another is tubal interruption at the time of cesarean section. The third is when serious systemic illness requires limiting the amount of pelvic surgery to the necessary minimum. In connection with the question whether the hysterectomy should be complete or supracervical, I simply state that, in addition to those whose cancers of the cervix are missed at the time of the incomplete operation, at least 1 of every 100 women so treated will develop this disease some time later. Moreover, 75 per cent of patients with cancer of the cervical stump die of the disease.

After the establishment of the menopause any bleeding from the uterine cavity indicates the presence of a surgical condition. There is no place for the use of hormones in the treatment of postmenopausal uterine bleeding. The condition may be nothing more than an endometrial polyp, which is likely to be found with the placental forceps or a clamp if missed by the curet. A palpable ovary in a postmenopausal patient is always pathologic. Even when no ovarian enlargement can be felt, the finding of hyperplastic endometrium signifies neoplastic ovarian activity. This may be benign but is always potentially malignant, as is the endometrium stimulated by it.

Radiation

The majority of women sterilized by radiation for abnormal bleeding associated with benign conditions, such as ovarian dysfunction and fibroids that are not submucous, get along very satisfactorily so far as later serious or disturbing pelvic troubles are concerned. That radiation is known to provide no immunity to the later development of genital cancer is no contraindication to its employment, for cancer might have developed anyway. On the other hand, according to recent studies, irradiation itself is probably carcinogenic in the susceptible woman. On occasion, a granulosa-cell tumor, thecoma or "thecomatosis" of the ovary appears to have its

etiology in previous irradiation. Also on occasion, atresia of the upper vagina or cervix from this treatment may prevent malignant growths at higher levels from manifesting themselves until too late. In other words, enough patients do have pelvic trouble sooner or later, even up to thirty years, after radiation for benign conditions to make one wish that the original therapy had been surgical or had consisted of temporizing with medical management of the bleeding until ovarian function had become adjusted. Therefore, in general, it seems better to treat fibroids surgically, at the same time avoiding unnecessary castration in younger women. Similarly, it seems better in general to omit radiation for dysfunctional uterine bleeding and, instead, to employ surgery in selected cases and hormones in the others. By selected cases I refer to quite a few women between the age of thirty-five and the menopause who have dysfunctional bleeding, and often premenstrual tension as well, and also prolapse and vaginal relaxation with symptoms therefrom. Many of these are best treated by vaginal, or complete abdominal, hysterectomy without removal of the ovaries, along with reconstruction of the vagina. In the absence of the uterus, simple ovarian dysfunction is harmless, causing little or nothing in the way of symptoms and no signs.

Hormones

Of the available hormones, progesterone and estrogen can be counted upon for predictable, immediate results in the control and regulation of dysfunctional uterine bleeding. Of the various ways of administering these ovarian hormones, I have found the following most effective:

For the patient who has been flowing more than seven days, even for months, at the time the diagnosis of dysfunctional uterine bleeding is made 25 mg of progesterone is injected intragluteally daily for five days during which the flow will slacken or cease. Two to four days after the last injection of this progesterone series a menstruation, often profuse, will ensue, ending in less than six days. The patient should be warned that the induced menstruation is the necessary evil of this efficient treatment. Normal cycles are likely to follow, for a time at least, but to make more certain of this result it is well to repeat the progesterone series at least once, starting eighteen to twenty-one days from the onset of the induced menstruation. Should irregular bleeding persist between progesterone-induced periods it is certain that some pathologic condition besides an abnormally functioning endometrium is inside the uterus. In other words, the failure of progesterone to be immediately therapeutic, when given as de-

scribed, points to an incorrect diagnosis and the necessity of investigation under anesthesia at once.

For the patient whose cycles are of normal length but whose bleeding is profuse, or continues up to eight days, and who often has premenstrual staining as well, the simplest therapy is the oral administration of estrogen starting with the onset, or during the first two days, of the period. Estrone sulfate, in divided doses totaling 10 mg daily, is taken for twenty-five days. To reduce expense, stilbestrol in daily doses of 5 mg, 10 mg or even 25 mg may be taken, on retiring, instead of estrone sulfate. Both of them may cause malaise in some women, in others a sense of well being is produced. The occurrence of bleeding between the sixth day and the end of estrogen treatment indicates the presence of some undiagnosed condition within the uterus. Two to six days after the cessation of medication uterine bleeding will begin. Though not profuse, it occasionally lasts up to eight days. Thereafter, normal catamenia may or may not ensue. Should excessive flow again appear early in a cycle, the estrogen treatment may be started at once and continued again for twenty-five days.

For this type of abnormal bleeding the progesterone series also has a place. If elected, it should be started between the eighteenth and twenty-first days of the cycle. Although in some women the ensuing catamenia may be profuse, it will not last so long. Moreover, there is a greater chance that normal catamenia will follow than after the estrogen treatment.

For the woman whose cycles are disturbingly shortened, whether or not her bleeding is profuse or prolonged, the progesterone series is begun eight days before the expected onset of a period. Or the estrogen treatment is given beginning at the start of flow. Here again, uninterrupted bleeding during estrogen treatment or following a post-progesterone menstruation is indicative of an incomplete diagnosis.

CONCLUSION

The management of abnormal uterine bleeding is fundamentally similar to the management of any other sign or symptom. It involves the diagnosis and treatment of definite and possible causes, the direct treatment of the complaint in the absence of determinable causes, and the therapy, so far as possible, of all other discoverable abnormalities. I am reminded of the illustrious statement by Dr. Francis W. Peabody that "The secret of the care of the patient lies in caring for the patient." I take the liberty of paraphrasing it as follows: the secret of the care of the patient lies in taking care of the whole patient.

MEDICAL PROGRESS

RESUSCITATION (Concluded)*

BOSTON

ASPHYXIA NEONATORUM

Asphyxia neonatorum is the most frequent emergency requiring resuscitation that is encountered in the delivery room. It is characterized by the absence of spontaneous effective respiration. The mechanism of the development of this type of respiratory arrest differs from those classified in the previous section, but the resultant pathological physiology has much in common with them.

The difference between asphyxia neonatorum and cardiorespiratory arrest is that in the latter both respiration and circulation cease and must be maintained artificially, whereas in asphyxia neonatorum, it is rare for the heart to stop beating and it is only the respiratory arrest that requires artificial correction. That this basic difference is generally accepted is well substantiated by the fact that artificial respiration in relation to asphyxia of the newborn is extensively discussed in the literature, while mention of cardiac resuscitation of the newborn is conspicuously rare. It is obvious that the newborn infant who has both respiratory arrest and cardiac arrest has declined to a state that is irreversible. As in all other cardiorespiratory accidents, the indispensable primary principle in the treatment of asphyxia neonatorum is the urgent necessity of delivering oxygen to the tissues before anoxic changes become irreversible. The most prominent anoxic manifestations are cardiac arrest and damage to the brain.⁹⁷

Pathological Physiology

The pathological changes in various organs contingent upon the anoxia in asphyxia neonatorum are typified by congestion of blood vessels, interstitial edema, diapedesis of blood cells, hemorrhages and necrosis of tissues.⁹⁸ In cases in which anoxia does not advance to the point of cardiac arrest the greatest danger is damage to the brain. Russ and Strong⁹⁹ indicate that prolongation of anoxia for more than two minutes after delivery of an infant will cause serious cerebral changes. Numerous reports and experiments prove that brain damage

can occur despite successful resuscitation and can result in crippling sequelae such as mental inferiority, diminution of ability to learn and mental dullness.¹⁰⁰⁻¹⁰¹ Studies of groups of children who had suffered varying degrees of asphyxia neonatorum revealed a high incidence of abnormal cerebral function, low intelligent quotients, retardation in later life and markedly affected behavior patterns often to a point incompatible with normal living, 26 per cent of the children were morons, imbeciles or idiots.¹⁰²⁻¹⁰⁴ These observations emphatically indicate that the major damage to the brain of the newborn infant from anoxia is manifested in later developmental abnormalities.

The outstanding pathological lesion at autopsy in cases of asphyxia neonatorum is the complete atelectasis of the lungs, which are airless, without crepitation and are a compact solid viscus having a fleshy parenchyma.¹⁰⁰⁻¹⁰⁵ Partial atelectasis may exist for long periods after respiration begins.¹⁰⁷

The alterations in blood chemistry in asphyxia neonatorum are not discussed, the reader is referred to the respective section of the collective review on this subject written by Little and Tovell.¹⁰⁰

Etiology

Little and Tovell¹⁰⁰⁻¹⁰⁵ point out in two excellent reviews on the subject of asphyxia neonatorum that the complete syndrome is usually the result of a combination of several of the numerous etiologic factors rather than any one factor in itself. They catalog the etiologic elements in three groups: those pertaining to the mother, those pertaining to the products of conception, and those pertaining to the labor and delivery.

There is a significant increase in the incidence of asphyxia of the newborn when the mother's age exceeds forty years.⁹⁹⁻¹⁰⁹ when the mother is a primipara or multipara after the eighth pregnancy.¹¹⁰⁻¹¹¹ and when the mother's health has been adversely influenced by cardiac disease, pulmonary disease, genitourinary infection, gastrointestinal disorders, metabolic disturbances and toxemia of pregnancy.¹¹¹⁻¹¹⁵

Abnormalities of the products of conception related to low viability of the germ plasm, immaturity of the fetus, congenital defects such as malformation of the respiratory and circulatory systems, and congenital debilities such as syphilis and erythroblastosis fetalis adversely affect the inci-

§Resident in anesthesiology, Boston City Hospital.

dence of neonatal asphyxia^{107, 116 119} Furthermore, the role of unfavorable position of the fetus in the uterus — particularly breech, transverse and occiput posterior presentations — is of appreciable significance

The factors pertaining to the labor and delivery that are regarded as of tremendous importance by Little and Tovell in unfavorably influencing the occurrence of asphyxia neonatorum are as follows: duration and type of labor — long, dry labor or long difficult labor associated with cephalopelvic disproportion^{113 114 120}, induction of labor with drugs such as quinine and Pituitrin^{111 112 120 121}, complications of labor — infarction of the placenta, low insertion of the placenta, placenta praevia and premature separation of the placenta, anoxia to the fetus originating in impaired circulation in the cord and anoxia to the fetus of uterine origin^{99 113 115 122 123}, type of delivery — version and extraction, high forceps, breech extraction, mid forceps, cesarean section and low forceps without episiotomy^{110 114 116 122 124}, and analgesic drugs and anesthetic agents and methods^{108 113}

In a series of 143 infants who died in the neonatal period from asphyxia and atelectasis, Roberts¹²⁵ found the close relation between intracranial damage coincident to difficult labor and this type of death very prominent, 55 of these infants evidenced intracranial damage. Confirmation of this observation is contributed by Russ and Strong,^{126 127} who also call attention to the importance of debris in the newborn infant's trachea as a cause of respiratory difficulty, particularly when delivery has been accomplished by cesarean section

Diagnosis and Classification

The diagnosis of asphyxia neonatorum is made by the simple observation that respiration is absent. Ascertaining the concomitant degree of anoxia is not so simple and is of major importance. Many classifications have been recorded to describe the conditions produced by progressing oxygen deficiency¹²⁸⁻¹³². The following classification offered by Flagg,¹³³ in which physical findings are the basis for diagnosis, is the one generally accepted and is the most practical from the therapeutic point of view

1 *Stage of Depression* baby does not breathe well, tendency to duskeness and recurring cyanosis, respiration free, but slow and irregular

2 *Stage of Spasticity* irregular, gasping, or shallow respiration occurring at long intervals, marked cyanosis of mucous membrane with blotching of skin or general pallor, the baby's gums close over the gloved fingertip, reflex reaction to suction of the pharynx, such as movement of facial muscles or extremities, if pharynx is exposed, pharyngeal reflex is sluggish or active and the glottic reflex is active

3 *Stage of Flaccidity* respiration occurs at long intervals or cannot be demonstrated, cyanosis or pallor, complete flaccidity of musculature, all muscle tone gone, jaw

completely relaxed, no resistance to suction or exposure of the pharynx, fluid is found in hypopharynx, apex beat may or may not be demonstrable

Prophylaxis

Since many of the etiologic factors capable of abetting the occurrence of asphyxia neonatorum are to some extent under the control of the physician much can be done in the way of preventive measures to reduce the incidence of this condition. Factors that are partially controlled by the physician are listed as follows by Little and Tovell¹⁰⁸: the health of the mother, congenital disease of the fetus, presentation and position, and the duration and type of labor and delivery. The last of these has further been highlighted by an analysis by Russ and Strong⁹⁹ of more than 1000 cases of asphyxia neonatorum enabling them to draw the conclusion that the prolongation of labor in association with a traumatic type of delivery is by far the most notable single cause. The emphasis upon the importance of conscientious and intelligent observation during the conduct of labor and the election of the safest and most suitable methods of delivery as vital prophylactic measures in asphyxia of the newborn is apparent.

Within the complete control of the physician are the induction of labor and the use of analgesics and anesthetics. The latter is important enough and controversial enough to demand some elaboration. Little and Tovell¹⁰⁸ have made a comprehensive study of this subject that enables them to conclude that there is a close causal relation between an increase in asphyxiated infants at birth and the use of analgesic and anesthetic drugs, in that every one of them may increase the incidence of this complication. They endorse and commend the approach of Grantly Dick Read to the problem of relief of pain in childbirth. This method is one in which a mental prophylaxis against fear is initiated in the expectant mother and renders the use of drugs unnecessary in the majority of cases.^{134 135} Read's^{136 137} practices have been gaining widespread recognition during recent years.

Though sounding a warning, Little and Tovell¹⁰⁸ do not condemn modern analgesia and anesthesia, "for the fault lies not so much in the drugs but in their methods of application." They signify that the following pharmacologic principles must be scrupulously adhered to when analgesics and anesthetics are administered: "each patient must be evaluated and treated on an individual basis, the dosage of the drugs administered must be the minimal effective dose, the physician must be in constant attendance to evaluate the effects of the agents on the woman in labor, cognizance must be taken of the presence of other factors besides those of analgesia and anesthesia that may tend to produce asphyxia neonatorum, and the use of

analgesics and anesthetics must be modified accordingly”

Treatment

In the treatment of asphyxia neonatorum there are two objectives to *deliver oxygen to the tissues* — as in any case of cardiorespiratory arrest, the saving of life and the avoidance of permanent brain damage will depend upon the successful execution of this principle by ventilation of the lungs, and to *protect the infant from harmful influences* — by institution of measures that safeguard normal physiology

Whereas the aims in the treatment of cardiorespiratory arrest are achieved one after the other, in the treatment of asphyxia neonatorum both propositions must be carried out simultaneously

Since asphyxia neonatorum is not complicated by cardiac arrest there is no need for the maintenance of circulation by cardiac massage

The first aim of resuscitation of the newborn is delivery of oxygen to the alveoli of the lungs by either stimulation of spontaneous respiration or artificial respiration

Stimulation of spontaneous respiration It must be borne in mind that this approach is justified only in the first stage of asphyxia, that of depression, in which the baby does not breathe well, respiration is slow and irregular. Gentle cutaneous friction, passive movements of the extremities and catheter aspiration of the nose, mouth, and pharynx are the acceptable procedures for this purpose^{115 123 141}

Artificial respiration If the infant does not breathe within thirty seconds of severing of the cord, artificial respiration must be instituted regardless of the stage of asphyxia^{99 115}. The most efficient method of applying artificial respiration to the newborn appears to be that performed by the employment of the Kreiselman resuscitator¹⁴²⁻¹⁴⁶. This mechanical resuscitator supplies an intermittent flow of oxygen under a controllable positive pressure, which may never exceed 15 or 16 mm of mercury. Oxygen is administered thirteen to fifteen times a minute, two or three seconds being allowed for inflation and two seconds for passive deflation, a positive pressure of 12 mm of mercury is applied at the outset for inflation of the lungs, and this may be increased to 14 or 15 mm. In the newborn this amount of positive pressure will not cause the chest to rise in the inspiratory phase because the lungs expand in a patchy distribution and it may take a long time for them to be thoroughly inflated. As Kreiselman¹⁴⁷ avers, the machine should be at hand in perfect working order for every delivery, and personnel expert in its use should be present.

If these conditions cannot be fulfilled and a simpler, immediately available means of administering artificial respiration must be resorted to, mouth-

to-mouth insufflation is considered the next choice^{78 107 142 148 151}

Disadvantages associated with this method are that it does not supply 100 per cent oxygen, there is the danger of the creation of excessive intrapulmonic pressure, which may cause fatal emphysema or pneumothorax, there is the possibility of overdistingending the stomach and rupturing it, and the procedure may lead to infection of the infant or of the operator¹⁵²⁻¹⁵⁷

Other means of artificial respiration employing resuscitators of the “suck and blow” type have been commended and condemned^{120 129 158-164}. Infant respirators of the Drinker type seem to have little practical value¹⁶⁵⁻¹⁶⁹

The dangers of excessive positive pressure mentioned above are present with all types of mechanical resuscitators, but they appear to be least likely with the Kreiselman apparatus, which provides the most adaptable means of positive pressure control¹⁷⁰. Finally, manual methods of artificial respiration in asphyxia neonatorum are observed to have no physiologic basis and are therefore of no value in the resuscitation of asphyxia of the newborn^{183 157 171-173}

The establishment and maintenance of a free air passage should be considered a part of the technic of artificial respiration. It is obvious that, without a free airway, oxygen cannot reach the alveoli of the lung. Gentle catheter aspiration of the nares, mouth, pharynx and, when necessary, the trachea and upper bronchial tree is advisable to remove aspirated material such as amniotic fluid, meconium and cellular debris, which may be the source of obstruction^{151 153 159 165 170 174}. Placing the baby in a head-down position helps serve the same purpose of draining material from the air passage, 15 to 30° of Trendelenburg position is considered optimal^{120 153 170}. In cases in which asphyxia has advanced to the stage of flaccidity, the collapsed glottic structures will produce obstruction of the airway. To obviate this obstruction, tracheal intubation is mandatory^{129 133 139 141 175 178}. The need for considerable skill in performing this procedure without trauma to the larynx is emphasized^{101 149 174}

The manipulations necessary to the establishment and maintenance of a clear airway are performed repeatedly as needed in conjunction with artificial respiration but in such a manner that artificial respiration is interrupted for only very brief periods. Performance of the initial aspiration of the upper respiratory tract is advisable the moment the head has been delivered and before the umbilical cord has been clamped^{101 133}

Formerly, the use of carbon dioxide was advocated as a stimulant to respiration in the resuscitation of asphyxia neonatorum, at present the use of carbon dioxide is considered useless or even harmful¹⁷⁹⁻¹⁸³

The status of drugs in the treatment of asphyxia neonatorum is identical with that of carbon dioxide or with that of drugs in the treatment of cardio-respiratory arrest, epinephrine, alpha lobeline, Pituitrin, camphor, coramine, picrotoxin, Metrazol, caffeine and strychnine have been proposed for consideration or have enjoyed the commendation of a number of observers^{150 157 174} More recently, the consensus is that they are likely to do more harm than good^{140 162 173}

The second aim of resuscitation of the newborn infant — that of maintaining normal physiology — is best furthered by scrupulous adherence to two simple principles. The first of these is the minimal handling of the infant to reduce the possibilities of shock, visceral lacerations and cerebral hemorrhage. There appears to be little justification for such "archaic methods of man-handling" as the Schultze giant swing, hot and cold tubbing, sprinkling the skin with ether, vigorous spanking, pummeling, dilating the anal sphincter and penile dorsal slit^{100, 120 172 184} Suspension by the feet to promote drainage of the respiratory tract, as formerly advocated, may aggravate the danger of cerebral hemorrhage. This suspended position is best avoided, and the optimal position of 15 to 30° Trendelenburg, as indicated above in the discussion of maintenance of a free air passage, should be utilized.

The second principle is immediate warmth. The importance of the retention of normal body temperature has been stressed^{99, 100 147} The practical importance of this measure has not been affected by theoretical objections¹⁸⁵

These essentials must be observed from the moment of birth throughout the period in which the newborn infant requires resuscitation.

Russ and Strong⁹⁹ believe that "the after-care of the newborn resuscitated baby is of equal importance to that of the resuscitation itself." This care includes preservation of oxygen physiology by inhalational therapy, close observation, placement in an incubator, withholding of feeding and the administration of a stimulant if necessary^{99 115 126 127}

* * *

The neonatal period is the most hazardous in life, here the mortality rate exceeds that of any other time, and the danger of permanent central-nervous-system damage is ever present¹⁴⁷ The persistent use of many faulty practices in the treatment of neonatal asphyxia may be an important factor contributing to fetal and neonatal mortality rates, which have improved but little during the past century^{107 133}

Although, in practice, resuscitation of the asphyxiated newborn infant remains primarily the province of the obstetrician,¹²⁶ in the words of Little and Lovell¹⁰⁸ "The anesthesiologist has come to join the obstetrician in being responsible not only for the safe and painless labor of the mother but, also,

for the safe deliverance of her infant, including, when necessary, the resuscitation of that infant."

ASPHYXIAL ACCIDENTS OUTSIDE THE OPERATING ROOM AND THE DELIVERY ROOM

The number of causes that may lead to asphyxial accidents in places other than the operating and delivery rooms is large and varied. Of these, the most important are inhalation of gases such as carbon monoxide, — illuminating gas and engine exhaust, — industrial gases — chemical, mine, refrigerants, smoke and chemical fumes, drowning, electrocution, drug poisoning from hypnotics, narcotics, sedatives and alcohol, and mechanical obstruction to respiration from smothering, strangulation, compression of the chest and choking — aspiration of foreign material and disease in the respiratory tract such as infection, tumor or allergy^{112 155 157}

In any of these conditions interruption of the oxygenation of the tissues is induced by either interruption of pulmonary ventilation — such as that which occurs in drug poisoning and electrocution, when the respiratory center is paralyzed, or as in drowning and mechanical obstructions of air passages, when effective ventilation becomes impossible, or interference with the oxygen-carrying power of the blood — as in carbon monoxide or nitrite poisoning, or finally arrest of the capacity of cells for utilizing oxygen (histotoxic anoxia) — as in cyanide poisoning¹⁰⁷

Although not of such vital significance as the lack of oxygen in asphyxial conditions, the retention of carbon dioxide in the blood contributes appreciably to the resultant asphyxial syndrome^{188 189}

When electrocution is the etiologic factor in an asphyxial accident, the respiratory arrest may be complicated by concurrent cardiac arrest¹²³

The location of asphyxial accidents has a notable bearing on their outcome¹⁹⁰ Obviously, the facilities available for resuscitative therapy are more immediately accessible in the emergency room of the hospital, the first-aid station or the doctor's office than in the home, at the roadside or river bank or in the field. Of equal significance is the personnel immediately available for initiation of life-saving measures, there can be no comparison between the effectiveness of the doctor or adequately trained first-aid technician and that of the casual passerby or inadequately informed lay person.

The classification of the stages of asphyxia given above in the section on asphyxia neonatorum is applicable to most of these asphyxial accidents. In the majority the initial stage is characterized by depression, which is followed by a period of struggle associated with spasticity and, finally, the third stage, in which there is complete flaccidity^{128 133}

A discussion of the pathological physiology, symptomatology, prophylaxis and special problems related to any one of these accidents, although fundamentally important to the physician, has been

omitted from this presentation. Most of this information may be obtained from Flagg's book on resuscitation.¹⁸³

Treatment

In the treatment of accidents of asphyxiation, it is imperative that two goals be attained: immediate delivery of oxygen to the alveoli of the lungs by artificial respiration, and support to the circulation, which is failing from anoxia.

Artificial respiration In accentuating the great importance of the time element in resuscitation, Comroe and Driggs¹⁸⁵ list the following basic principles that must be adhered to regardless of the nature or place of the accident: "The most immediately available method must be employed instantly" and "as soon as possible the most efficient method of artificial respiration should replace the emergency measure."

If, when a victim of an asphyxial accident is encountered, there are no facilities at hand for providing resuscitation, which is most often the case, the only method immediately available is manual artificial respiration.^{69 128 191} Of the several methods the generally approved technic is that of Schaefer, which employs rhythmic compression of the lower thorax with the patient in the prone position.^{34 192 193}

The manual methods of artificial respiration, even though properly executed, do not provide sufficient respiratory exchange and should not be regarded as definitive but only as a temporary emergency measure.^{188 194-197}

The means of providing efficient artificial respiration to replace the emergency manual procedure include the following:

Rhythmic inflation of the lungs by use of a mechanical apparatus Of these the simple and small bellows-type device introduced by Kreiselman appears to offer definite advantages in that it accomplishes adequate pulmonary ventilation with air or oxygen, when it is available, it is compact, inexpensive and easily portable.¹⁴⁸ Other more elaborate machines for performing artificial respiration are obtainable on the market. Among these are the E and J, the Emerson, B-K, Davis, and H and H inhalators and resuscitators.^{129 133 195} They supply 100 per cent oxygen or a mixture of oxygen and carbon dioxide by either alternating positive or negative pressure from 15 to 25 mm of mercury. These machines are mechanically accurate but not quite so easily transportable.

The tilting method of Ege This method utilizes the tilting of the patient 45° in the head-up position (inspiratory phase), followed by a sharp reversal to 45° in feet-up position (expiratory phase). Respiratory exchange is produced by movements of the diaphragm in response to ascent and descent of the abdominal viscera with the sudden changes in position. The respira-

tory exchange afforded is better than that with manual methods, and although this means of artificial respiration is highly recommended, its efficiency does not approximate that of rhythmic inflation of the lungs by apparatus employing positive pressure. Further limitations are difficulties encountered in transporting or improvising the necessary apparatus. Ege's tilting method does contribute two features of value irrespective of its utility for artificial respiration. These are a beneficial massaging effect on the heart and the facilitation of drainage from the respiratory tract when it is used in the treatment of a victim of drowning.^{78 185 199}

Insufflation of oxygen with endotracheal intubation Insufflation of oxygen without respiratory excursions of the chest can provide oxygenation and might be employed in the treatment of asphyxia, however, it should not be used for more than a few minutes without the addition of rhythmic manual compression of the chest because the accumulation of narcotic concentrations of carbon dioxide will occur.^{185 200-202}

The establishment and maintenance of an unobstructed airway is a prerequisite of artificial respiration. None of the methods of performing artificial respiration will be effective without patency of the air passage. It is because automatic machines for supplying artificial respiration are so often employed with disregard to respiratory obstruction that they have been generally considered both hazardous and unscientific.¹⁸³ The same observation is applicable to other methods of artificial respiration.

One of the most frequent causes of interference with the free passage of air is an abnormal position of the pharyngeal structures as represented by the backward displacement of the tongue, which is more prone to occur in the supine position than when the victim is face down.¹⁹⁵ Regardless of the type of artificial respiration employed, the operator must be constantly on the alert for this possibility.^{183 181} Proper support of the jaw, pulling the tongue forward and insertion of nasal or oral "airways" are simple measures and may contribute to overcoming the difficulty, on the other hand, they may be inadequate.^{112 116} The passage of an endotracheal tube, which requires experience and often a good deal of time, assures a patent respiratory passage and is urged by Flagg for all patients who have declined to the stage of flaccidity.^{183 203}

Other causes of respiratory obstruction are occlusion by some foreign body or by a pathologic deformity of the respiratory tract. These may be the initial causes of asphyxial accidents as illustrated by the example of a victim of choking.^{107 133 156} In the event of a pathologic deformity or inhalation of a foreign body, when simple measures such as suspending the victim head down and finger exploration of the throat have failed to

dislodge the obstructing material, emergency tracheotomy or intubation will be required ^{133 181}

Several factors such as the nature of the obstruction, the stage of asphyxia, the available facilities and familiarity with these technics determine whether tracheotomy or endotracheal intubation should be resorted to. Gross deformity of the glottis may render intubation impossible. The victim in the stage of spasticity is unsuited for intubation ¹³³. Patients in the first or second stage of asphyxia who have an appreciable respiratory exchange irrespective of the nature of the obstruction may be given oxygen with maximum available intermittent positive pressure synchronized to the patient's respiration during transportation to the nearest hospital, where immediate tracheotomy, laryngoscopy, bronchoscopy or intubation may be performed ^{133 181 201 208}

After tracheotomy, if the resuscitating apparatus can be attached to the tracheotomy-tube opening so as to be airtight, oxygen under intermittent positive pressure should be administered. If it is not possible to supply such an airtight system, a constant flow of oxygen should be insufflated through the tracheotomy opening while manual artificial respiration is simultaneously applied ^{107 133 181 204}

The causes of respiratory obstruction enumerated above may be further aggravated by aspiration of regurgitated gastric contents or other fluids and by the presence of excessive secretions. Brief and repeated catheter suction and postural drainage of the patient to remove these products should be utilized as necessary ^{107 133 181}

The gas used for artificial respiration should always be 100 per cent oxygen except in carbon monoxide poisoning ²⁰⁵⁻²⁰⁸. It has been demonstrated that with the addition of 5 to 10 per cent of carbon dioxide to the inhaled atmosphere, the elimination of carbon monoxide will be faster and the availability of oxygen to the tissues will be increased ^{107 209-211}

The second aim of resuscitation in asphyxial accidents—that of providing support to the failing circulation—includes measures to combat shock and stimulate heart function ^{212 214}

If facilities permit, fluid therapy should be administered intravenously, and measures by which the venous return to the heart can be increased, such as the Trendelenburg position, raising the legs to the vertical position ("autogenous transfusion") and application of tourniquet to the extremities, should be utilized ²¹⁵⁻²¹⁹. Normal body temperature should be maintained, but care must be taken not to overheat the patient ²²⁰

Employment of drugs that stimulate circulation such as epinephrine, ephedrine and related amines should be resorted to only if complete oxygenation has been established ^{215 218 221}

During the aftercare when the patient has regained spontaneous respiration, further inhalation

and fluid therapy, supervision of a free respiratory exchange, attention to bladder and bowel functions and the maintenance of body temperature are in the realm of general nursing care but are essential components of thorough treatment

* * *

A trend that had developed over the past twenty years has led to an undesirable situation regarding asphyxial accidents. This situation is characterized by overzealous activities of lay rescue squads and at the same time a lack of professional interest in problems of resuscitation on the part of the physician. Insufficient essential knowledge of the anatomy of the respiratory tract, physiology of respiration, pneumatology, physiology of anoxia, pathological physiology and diagnosis of asphyxia is an obvious limitation to the capabilities of the lay rescuer. That this limitation is often not appreciated is evidenced by the calls to lay rescue squads that originate even from the operating and delivery rooms. The attitude of the medical profession frequently implies that the treatment proffered by the mechanical performance of the lay squad, aided by the inhalator, leaves nothing more to be desired ¹³³

The resolution by the American Medical Association to encourage instruction of medical students and postgraduates in pneumatology and in the treatment of asphyxial accidents, the activities of the Society for the Prevention of Asphyxial Deaths, Incorporated, and the inclusion of resuscitation as a basic subject in the specialty of anesthesiology, along with other efforts on the part of the medical profession, are laudable measures for the improvement of the situation ^{222 223}. It is hoped that in the future, in the words of Flagg ¹³³ "When the average physician looking upon impending asphyxial death is shocked into a realization that here and now is the supreme test of his life-saving skill as a physician, resuscitation will cease to be relegated to the care of those lay groups whose services have been and continue to be a bridge to span the period between helplessness and adequate medical care."

We gratefully acknowledge the co-operation of the residents and interns of the Anesthesia Department of the Boston City Hospital

dislodge the obstructing material, emergency tracheotomy or intubation will be required^{133 181}

Several factors such as the nature of the obstruction, the stage of asphyxia, the available facilities and familiarity with these technics determine whether tracheotomy or endotracheal intubation should be resorted to. Gross deformity of the glottis may render intubation impossible. The victim in the stage of spasticity is unsuited for intubation.¹³³ Patients in the first or second stage of asphyxia who have an appreciable respiratory exchange irrespective of the nature of the obstruction may be given oxygen with maximum available intermittent positive pressure synchronized to the patient's respiration during transportation to the nearest hospital, where immediate tracheotomy, laryngoscopy, bronchoscopy or intubation may be performed.^{133, 181 204-206}

After tracheotomy, if the resuscitating apparatus can be attached to the tracheotomy-tube opening so as to be airtight, oxygen under intermittent positive pressure should be administered. If it is not possible to supply such an airtight system, a constant flow of oxygen should be insufflated through the tracheotomy opening while manual artificial respiration is simultaneously applied.^{107, 133 181 201}

The causes of respiratory obstruction enumerated above may be further aggravated by aspiration of regurgitated gastric contents or other fluids and by the presence of excessive secretions. Brief and repeated catheter suction and postural drainage of the patient to remove these products should be utilized as necessary.^{107 133 181}

The gas used for artificial respiration should always be 100 per cent oxygen except in carbon monoxide poisoning.^{205 208} It has been demonstrated that with the addition of 5 to 10 per cent of carbon dioxide to the inhaled atmosphere, the elimination of carbon monoxide will be faster and the availability of oxygen to the tissues will be increased.^{107 209 211}

The second aim of resuscitation in asphyxial accidents—that of providing support to the failing circulation—includes measures to combat shock and stimulate heart function.²¹²⁻²¹⁴

If facilities permit, fluid therapy should be administered intravenously, and measures by which the venous return to the heart can be increased, such as the Trendelenburg position, raising the legs to the vertical position ("autogenous transfusion") and application of tourniquet to the extremities, should be utilized.^{215 219} Normal body temperature should be maintained, but care must be taken not to overheat the patient.²²⁰

Employment of drugs that stimulate circulation such as epinephrine, ephedrine and related amines should be resorted to only if complete oxygenation has been established.^{215, 218 221}

During the aftercare when the patient has regained spontaneous respiration, further inhalation

and fluid therapy, supervision of a free respiratory exchange, attention to bladder and bowel functions and the maintenance of body temperature are in the realm of general nursing care but are essential components of thorough treatment

* * *

A trend that had developed over the past twenty years has led to an undesirable situation regarding asphyxial accidents. This situation is characterized by overzealous activities of lay rescue squads and at the same time a lack of professional interest in problems of resuscitation on the part of the physician. Insufficient essential knowledge of the anatomy of the respiratory tract, physiology of respiration, pneumatology, physiology of anoxia, pathological physiology and diagnosis of asphyxia is an obvious limitation to the capabilities of the lay rescuer. That this limitation is often not appreciated is evidenced by the calls to lay rescue squads that originate even from the operating and delivery rooms. The attitude of the medical profession frequently implies that the treatment proffered by the mechanical performance of the lay squad, aided by the inhalator, leaves nothing more to be desired.¹³³

The resolution by the American Medical Association to encourage instruction of medical students and postgraduates in pneumatology and in the treatment of asphyxial accidents, the activities of the Society for the Prevention of Asphyxial Deaths, Incorporated, and the inclusion of resuscitation as a basic subject in the specialty of anesthesiology, along with other efforts on the part of the medical profession, are laudable measures for the improvement of the situation.^{222 223} It is hoped that in the future, in the words of Flagg¹³³ "When the average physician looking upon impending asphyxial death is shocked into a realization that here and now is the supreme test of his life-saving skill as a physician, resuscitation will cease to be relegated to the care of those lay groups whose services have been and continue to be a bridge to span the period between helplessness and adequate medical care."

We gratefully acknowledge the co-operation of the residents and interns of the Anesthesia Department of the Boston City Hospital.

stopped drinking and "has not touched a drop since."

Physical examination revealed an acutely ill, well developed, well nourished moderately pale man. The skin was hot and dry. There was a single "spidery angioma" on the left upper arm. A dilated venule that "seemed to end abruptly" was found on the posterior pharynx. The chest was clear. The heart was slightly enlarged to the left. The rhythm was regular, and the sounds were hyperactive. A Grade II systolic murmur was heard over the entire precordium and was transmitted to the axillas and neck. The abdomen was nontender and not distended. The liver edge was barely palpable at the liver margin. The spleen was not felt. Peristalsis was diminished. Rectal examination was negative.

The temperature was 102.6°F, the pulse 130 and the respirations 30. The blood pressure was 80 systolic, 50 diastolic.

The hemoglobin ranged from 11 to 12.5 gm. The white-cell count was 17,000, with 78 per cent neutrophils. The platelets were normal morphologically. There was slight erythrocytic hypochromia. The urine specific gravity was 1.025. The sugar test was brown, but intravenous glucose solution was being administered. A stool was brown and gave a + guaiac reaction.

Throughout his short hospital course the patient remained acutely ill, constantly febrile and in a constant state of shock. At intervals of one to four hours he vomited copious quantities of bright-red blood, losing a total of 4500 cc. by hematemeses. Parenteral injection of vitamin K and 6000 cc. of blood were administered during the first twenty-four hours. Attempts at esophageal tamponade were unsuccessful because of vomiting. Large doses of sedatives were given, and a state of semidelirium developed. At the end of twenty-four hours his condition stabilized somewhat. The blood pressure rose to 140 systolic, 70 diastolic, but tachycardia persisted. An emergency barium study of the esophagus was reported as showing "unequivocal varices." Twelve hours later there was a sudden drop in blood pressure to 80 systolic, 60 diastolic. Respiratory and cardiac failure quickly ensued despite the rapid administration of 1000 cc. of blood.

Large amounts of blood welled into the pharynx, and the patient died thirty-six hours after entering the hospital.

DIFFERENTIAL DIAGNOSIS

DR MILES P. BAKER: This is a brief story of massive hematemeses in a forty-eight-year-old man who was brought to the hospital bleeding to death, with a history of a similar but less severe hematemeses five months before, unexplained as to etiology.

The problem facing his physicians, primarily, was to save his life. That involved certain diag-

nostic procedures, because they had to consider the possibility of bleeding peptic ulcer for which surgical treatment might be necessary—hence, I suppose, the so-called emergency barium study of the esophagus done during the twenty-four hours preceding death. Was that only a fluoroscopic observation, Dr Mallory?

DR TRACY B. MALLORY: I cannot be sure.

DR BAKER: The data regarding the first hematemeses were, I suppose, obtained from the family. I think that one of the critical findings during that first episode of hematemeses was the jaundice. It is noted in the protocol as developing promptly after transfusions, which led to reactions. Reactions following transfusion are generally reported as occurring in approximately 6 per cent of cases, even when all reasonable precautions are taken. Reactions are not usually hemolytic—usually mild, febrile or urticarial. It is well to remember that chill following transfusion does not necessarily mean that hemolysis has taken place. The rule, as far as jaundice is concerned following transfusion, is that it can be expected about twelve hours after transfusion if a hemolytic reaction has taken place, it is a transient affair and is no longer observed after the passage of three or four days, at the most. My impression, then, of this comment that jaundice promptly developed is that jaundice was observed at that time but may have been present for some time before. Often, people recognize jaundice at a given time, but actually it has been there quite a while. Jaundice that took two weeks to fade, I would think, was much more likely due to liver disease. It would be consistent with an episode of jaundice in the course of cirrhosis of the liver. Jaundice in cirrhosis of the liver is statistically common, but it has to be remembered that it is of ominous prognostic significance. Once it appears, it generally does not disappear entirely, as the jaundice appears to have done in this man over his convalescent period of three or four months between hematemeses. I should say that the chances of having jaundice with cirrhosis of the liver, as a result of functional disturbances of the liver cells, and having it disappear would be no more than one chance in five or six—so that my stand that this jaundice was due to liver disease rather than any hemolytic reaction is something of a far cry. But I would prefer it to explaining the jaundice on the basis of hemolytic reaction to blood transfusion.

We have no evidence of any chemical studies to support either explanation for his jaundice. The prothrombin time of 75 per cent of normal is barely below what is found in a good many people when prothrombin times are determined on the wards. Of course, it must be below 20 per cent of normal before one runs into any serious hemorrhagic trouble, and this one finding is rather a weak reed for a diagnosis of cirrhosis of the liver. Could a prolonged prothrombin time be the one abnormal liver-function

EDITH E PARRIS, *Assistant Editor*

CASE 35371

PRESENTATION OF CASE

A forty-eight-year-old truck driver was admitted to the hospital because of severe hematemesis

Five months before admission, while in a distant city, the patient suffered a sudden severe hematemesis. Several "liver-chemistry studies" performed at that time were normal, except the prothrombin time, which was 75 per cent of normal. The findings on a gastrointestinal series were somewhat equivocal but suggested esophageal varices, gastritis and "possible ulcer in the first portion of the

duodenum." He was given five transfusions, "the last four of which gave him reactions." Jaundice promptly developed, and the icteric index rose to 18 units. Administration of vitamin K failed to improve the prothrombin time. Bleeding stopped, and over the ensuing two weeks the jaundice faded. He lost 15 pounds in weight during the illness, and spent the following three months in convalescence before returning to his truck route. During the convalescent period an additional transfusion was administered to the patient without event. Eight teeth were extracted, after which blood oozed from the gums for what was considered a prolonged period. The gastrointestinal series was repeated, but no abnormalities were discovered. He returned to work and felt well, remaining free of symptoms until the day of admission. While driving his truck he "felt sick" and then suddenly vomited a large amount of blood. During the five hours required to transport him to the hospital, he had five additional episodes of vomiting. He felt weak, nauseated and intensely thirsty but not faint or "sweaty." Since the onset he had had one brown bowel movement.

His mother had died of cancer. His wife had suffered from tuberculosis at the time of their marriage, twenty years before admission, but had been in good health at the time of her husband's illness.

As a young man the patient had drunk large quantities of beer, up to several quarts a day. In recent years he had reduced the intake to a bottle a day. Six months before entry he spontaneously

I would like to vindicate the outside x-ray findings. This man had large and definite esophageal and gastric varices and also a very severe gastritis, which was hemorrhagic in part. There was a deep crater-like lesion of the duodenum that looked at first glance like a deep penetrating ulcer. In its center was a ridge that proved to be the common bile duct. It was lined by normal mucous membrane and represented a congenital diverticulum. The ampulla of Vater is a common site for such a lesion. On x-ray examination it could readily be interpreted as an ulcer crater. The stomach showed on microscopical examination a severe gastritis associated with the presence of a great many bacteria on the surface—a rather unusual finding in the stomach, since most stomachs are sufficiently acid so that organisms do not grow.

DR ALFRED KRANES: Were you able to demonstrate varices?

DR MALLORY: They were very marked and abundant, and I think they were the primary cause of hemorrhage, although the lesion in the stomach must have bled to some degree as well.

A PHYSICIAN: Was the spleen enlarged?

DR MALLORY: Only slightly. He had bled enormous quantities. The spleen, at autopsy, following hematemesis, is frequently considerably smaller than it has been during life.

Microscopical examination of the liver showed something that I believe casts light upon the transient episode of jaundice five months before the terminal events. There were many small foci of fresh, infarct-like necrosis irregularly scattered throughout the organs. Usually, they were about 1 mm in diameter and involved part or all of a small nodule of regenerated liver cells. This is not an infrequent finding in cirrhosis when severe hematemesis has preceded death by a number of hours. My explanation is that the blood supply in these scarred, irregularly reconstructed organs is no longer uniform. When hemorrhage from varices lowers the portal pressure and shock lowers the arterial pressure, ischemic damage occurs at susceptible points and liver function may be significantly depressed. It is not rare to see transient ascites develop following hematemesis, and jaundice, though less usual, would develop by the same mechanism and disappear when the liver circulation once again improved.

CASE 35372

PRESENTATION OF CASE

A two-day-old baby girl entered the emergency ward in an oxygenated incubator with pronounced abdominal distention and vomiting.

This was the mother's first pregnancy and was without incident. Delivery, at an outside hospital, proceeded normally, prophylactic low forceps being

used, breathing was spontaneous, and the cry was vigorous. The infant remained active and apparently well for the first twenty-four hours. On the second day of life, her color was described as "dusky," and she vomited dark, bloody fluid with her first feeding. Each subsequent feeding elicited vomiting. A small amount of meconium was said to have been passed by rectum on one occasion only. An enema produced only a small amount of meconium in addition to a 2-cm plug of mucoid material. On the next morning she was considered normal by an examining pediatrician. Late that afternoon, "caput medusae" of the abdomen, distention and cyanosis were noted. The baby continued to vomit feedings and became progressively cyanotic and more distended. She entered this hospital fifty-six hours after birth.

Physical examination revealed a very ill infant, with cyanosis, which was more evident over the lower half of the body. Respiration was shallow and rapid, coarse, squeaky rales were present throughout both lung fields, more intense on the right. No cardiac murmur was noted. The abdomen was greatly distended without auscultable peristaltic sounds. No meconium was obtained on rectal examination. The anterior fontanel did not bulge.

The temperature was 98.2°F.

The white-cell count was 8200. The eosinophilic count was 0 per cent.

Radiograms in the supine position revealed marked upward displacement of both leaves of the diaphragm and compression of the lung fields by a distended abdomen. There was gaseous distention of the stomach and several loops of small bowel. In the right lower quadrant there was a C-shaped loop of dilated gas-filled bowel, possibly small bowel, measuring 2.5 cm in diameter. Throughout the abdomen there was a diffuse haziness indicative of intra-abdominal fluid.

A stomach tube was passed, and greenish substance obtained. A rectal tube was inserted. Infusions, chemotherapy and supportive measures were instituted.

Further radiograms in both the supine and upright positions revealed, in addition to the previous findings, a decompressed stomach and a large quantity of free gas and fluid in the peritoneal space (Fig 1).

With continuous oxygen administration, abdominal paracentesis was done. One hundred and five cubic centimeters of dark brownish fluid with specks of yellowish-white material was obtained. Smears of this revealed copious gram-negative rods and gram-positive diplococci. Cyanosis increased. Respiration became irregular with periods of apnea. Artificial respiration was begun. Epinephrine, 0.5 cc, was given intracardially. Despite continued artificial respiration, cyanosis deepened and the infant died five hours after admission.

test in cirrhosis of the liver? Yes, it could be, but it is uncommon

The significance of the bleeding from the gums during the period of convalescence is, I think, very dubious. We cannot lay any stress on it. At the time of his first and final admission here one single spider angioma was observed on the left upper abdomen. This may or may not have been of really diagnostic importance. Spider angiomas are found in varying percentages of patients reported with cirrhosis, depending on the interest of the observer and the carefulness of the examination. They have been reported by careful observers in 75 per cent of a series of proved cases of portal cirrhosis. I can recall a case presented here this spring in which a single spider angioma observed by a visiting physician — and not previously recognized as such by others — was associated with proved fatty changes in the liver. In that case it was a very important diagnostic point. Spider angiomas do occur in other diseases — in vitamin B complex deficiency, notably. But the genuine article is usually associated with hepatic disease, and that is usually portal cirrhosis. I am surprised at the height of the hemoglobin figure, and cannot explain it in a patient who was in shock. I suppose it was taken at the time when he had just had a transfusion and had not yet begun to bleed again. I presume, with the roentgenologic observation, that there were unequivocal esophageal varices, that the medical officers in charge of the case expected that at post-mortem examination cirrhosis of the liver would be found. Is it possible to have such an advanced stage of cirrhosis of the liver that esophageal varices are present and detectable by x-ray study and bleed, with normal liver-function tests? It must be the exception to the rule. One roentgenologist who has had a great deal of experience with the demonstration of esophageal varices tells me that although he could not put his finger on an individual case he believes that they must occasionally occur. We do not know what liver-function studies were done five months before admission, and no attempt could be made at this admission for further studies, but it would surely not be unreasonable to assume that bleeding esophageal varices were the cause of this man's death.

What other possibilities might there be? Peptic ulcer is the commonest cause of massive hemorrhage in the upper gastrointestinal tract, accounting for probably 60 to 75 per cent of such cases. We must consider it in any event — if only on the basis that the x-ray examination five months before suggested an acute duodenal ulcer. The association of cirrhosis of the liver and duodenal ulcer has been commented on several times, whether it is more than a coincidence or not is not established. So, even if this man did have unequivocal evidence of esophageal varices just prior to death he still may have

been bleeding fatally from a duodenal ulcer. Such an explanation has been advanced under similar circumstances in cases presented here. If this man had cirrhosis of the liver, he may have been bleeding, if not from esophageal varices, from a much engorged mucous membrane in the upper third of the stomach, sometimes found in such cases either in association with, or in the absence of, erosions of varices in the lower end of the esophagus.

It is noted here that the hematemesis was described as "copious quantities of bright-red blood." That might be interpreted as arterial blood, more typical, perhaps, of the bleeding from duodenal ulcer or gastric ulcer than from esophageal varices. On the other hand, it is so characteristic for the patient with bleeding esophageal varices to have blood well up into the pharynx that there may be evidence here on one side as well as the other.

My impression is that this man had cirrhosis of the liver and bleeding esophageal varices. There may have been an associated duodenal ulcer, which was a primary factor in his bleeding, but we have no more than a suspicion for it.

A PHYSICIAN Did he have an enlarged spleen?

DR. BAKER Not enlarged, so I should think one had no reason to consider congestive splenomegaly — Banti's disease.

CLINICAL DIAGNOSIS

Ruptured esophageal varices
Laennec's cirrhosis?

DR. BAKER'S DIAGNOSES

Portal cirrhosis
Esophageal varices, with massive and fatal hematemesis
Duodenal ulcer?

ANATOMICAL DIAGNOSES

Portal cirrhosis of liver, alcoholic type
Esophageal and gastric varices, with ulceration and hemorrhage into gastrointestinal tract
Gastritis, acute
Diverticulum, congenital, of duodenum

PATHOLOGICAL DISCUSSION

DR. MALLORY Autopsy on this man showed a cirrhotic liver. It was enlarged, very finely granular, tough, pale and evidently fatty. Its gross appearance and the subsequent microscopical findings were characteristic of what we ordinarily call alcoholic cirrhosis of the liver, despite the history of the consumption of nothing stronger than beer, and not even that for the last six months. One can interpret that as one chooses. The man was a truck driver, and a written record of alcoholism might have caused him to lose his job so I do not believe one can take it at its face value. Moreover, truck drivers as a group eat very well, so that malnutrition is very unlikely unless provoked by alcoholism.

Thrombophlebitis of the portal system can lead to gangrene of the bowel and subsequent rupture. I doubt whether such a process could take place in so short a time as the history indicates. Cyanosis, more evident in the lower extremities, suggests involvement possibly of the vena cava and iliac veins, most likely by compression. The absence of peristalsis suggests peritonitis and ileus.

Before going on to the x-ray studies, I believe we should say a word or two about the meconium. As one notes, very little was passed. The mucoid plug is a normal finding—often referred to as a “meconium plug.” In the normal infant this is usually followed by the characteristic tarry, sticky meconium. After the plug was passed no further meconium was reported. Rectal examination failed to reveal any. This suggests obstruction from either atresia or inspissated meconium. A helpful test for atresia is the absence of cornified cells in the meconium. These cells from the vernix caseosa are desquamated into the amniotic fluid, which is swallowed by the fetus in utero. If no atresia exists, their presence can be detected in the meconium.

May we see the x-ray films?

DR STANLEY M. WYMAN: In the first film, which is of rather poor quality, the stomach is distended and the gas in the abdomen obscures the liver shadow, with a C-shaped loop of dilated bowel in the right lower quadrant. The diaphragm, as recorded, is displaced upward, and the lung fields are slightly compressed. A short time later, after the stomach had been aspirated, the gas in the stomach is decreased to normal, but the C-shaped loop of bowel in the left midabdomen remains. Again, gas is seen obscuring the shadows of the liver and spleen. This next film was taken at the same time in the upright position and shows a large quantity of gas with fluid in the abdomen. I do not see any evidence of gas in the colon.

DR BURGIN: Have you any idea where the C-shaped loop would be?

DR WYMAN: I should say that it was the ileum.

DR BURGIN: The haziness reported in the first set of films as fluid need not indicate peritonitis. In infants, distention of the intestines alone may cause fluid to accumulate. Subsequently, there was evidence of rupture of a hollow viscus—obviously bowel—and the presence of the usual flora in the newborn: colon bacilli and, I presume, enterococci.

I believe the evidence points to intestinal obstruction due to an intrinsic lesion relatively low down in the bowel, which eventually resulted in rupture. The intestinal wall of the newborn is extremely thin, and rupture occurs relatively quickly if the distention is not relieved. I consider atresia the most likely cause of the lesion, although inspissated meconium—“meconium ileus”—remains an outside possibility.

In summary, early persistent vomiting, increasing generalized abdominal distention, absence of stools, accumulation of fluid and finally x-ray evidence of gas in the peritoneal cavity and distention of stomach and loops of bowel point to a diagnosis of atresia of the small bowel with rupture. On the basis of statistical frequency the atresia was most likely in the ileum. There should have been evidence of rupture, peritonitis, atelectasis and possibly some pneumonia.

DR F. DENNETTE ADAMS: In babies would there be distention enough to cause cyanosis?

DR BURGIN: Certainly the newborn can become distressed following a meal causing difficulty in breathing. Mothers report that, after eating, a baby may have difficulty in breathing due to a distended stomach but not enough to produce cyanosis. I passed over the possibility of stenosis; there may be a patency of only 1 or 2 mm in diameter, and for all practical purposes this may give signs and symptoms of obstruction.

CLINICAL DIAGNOSES

Congenital atresia of small bowel
Peritonitis due to perforated viscus

DR BURGIN'S DIAGNOSES

Congenital atresia of the bowel (ileum), with rupture
Colon-bacillus peritonitis
Pulmonary atelectasis
Pneumonia?

ANATOMICAL DIAGNOSES

Congenital defect of mesentery, with volvulus and perforation of ileum
Peritonitis
Pulmonary atelectasis, severe

PATHOLOGICAL DISCUSSION

DR TRACY B. MALLORY: At autopsy when the abdomen was incised large amounts of hemorrhagic fluid exudate were found. The entire small bowel was dilated, the dilatation increasing as one progressed downward from the duodenum. The cause of this was discovered as the lower ileum was reached. A congenital defect was found in the mesentery through which a loop of ileum had protruded and then twisted on itself, forming a volvulus. Evidently at a later period three small perforations had developed in the gangrenous bowel of the volvulus.

Regarding the cyanosis, the astonishing thing at autopsy was that the child had breathed at all. The lungs were as totally atelectatic as those of a newborn baby who has never taken a breath. It was difficult to understand how the child could have lived long enough to develop such persistent and complete collapse.

DIFFERENTIAL DIAGNOSIS

DR. LEO B. BURGIN In brief, we are faced with the problem of determining the cause of a series of events following one another rapidly in a two-day-old infant: persistent vomiting, abdominal distention, cyanosis, paralytic ileus, intra-abdominal fluid

FIGURE 1

and terminally gas and probably pus in the peritoneal space, with death at sixty-one hours.

A number of possibilities present themselves, in particular, congenital malformations of the gastrointestinal tract, meconium ileus and infection. Other possibilities may come to mind as the discussion proceeds.

Vomiting as a single episode or with occasional repetition is not uncommon in the normal newborn. The first episode described "dark bloody fluid." This may have had no further significance than that it represented aspiration of the blood at the time of delivery. There was no repetition of this

It was early for hemorrhagic disease of the newborn. Subsequently, the infant vomited at each feeding. We are not told the nature of the vomiting, whether it was projectile or merely regurgitation. Also, no description of the vomitus is offered. Later, "greenish" material was aspirated from the stomach, suggesting the presence of bile. An obstructive lesion under such circumstances would exist below the ampulla of Vater. Such an obstruction might be in the nature of atresia or stenosis, inspissated meconium or possibly malrotation of the cecum—the unrotated cecum lying across the lower end of the duodenum.

Vomiting is a frequent occurrence in infection. Although infection existed terminally as peritonitis, there was nothing to indicate its presence earlier. The white-cell count and temperature on admission were normal. Overwhelming infection or sepsis in the newborn may be present with a normal temperature and white-cell count. The eosinophilic count of 0 per cent merely indicates adrenal response or perhaps more accurately the "alarm-reaction" response to an overwhelming insult to the body. The absence of a bulging fontanel rules out intracranial vomiting, though not absolutely.

The rales in the chest might indicate pneumonia, but very likely some atelectasis and compression from a distended abdomen were largely responsible. One cannot rule out pneumonia.

The persistent vomiting was followed by abdominal distention, which appears to have been generalized. Obstruction in the region of the duodenum is apt to cause distention in the region of the epigastrium. Peristaltic waves are often visible. None were reported here.

It appears that in this case, the distention being generalized, any obstruction must have been lower down. This might rule out a malrotated cecum, which commonly lies across the third part of the duodenum. I might point out that in this anomaly the mesentery of the small bowel may lack the normal fixation, so that volvulus of the midgut, with gangrene and necrosis, may occur and might conceivably give the picture described. As we have indicated, distention caused by the unrotated cecum would be localized to the epigastrium—at least in the beginning. I assume that the generalized distention recorded here appeared almost at once. Also, the obstruction would not have been complete in the beginning, and we would have evidence of more stools or meconium to indicate patency of the gut.

The sudden appearance of a "caput medusae" suggests involvement of the portal vein, either from compression by distended gut or possibly from thrombophlebitis. The source of infection might be via the umbilicus, although the record says nothing about its appearance. It could look normal at this time and still be the source of infection.

parts of the country and had kept in a frozen state. They were unable to isolate the virus from two pools of feces, one obtained in New York in 1944 and the other in Los Angeles in 1948, both these pools yielded poliomyelitis virus on inoculation of monkeys. They did, however, recover both the new virus and the poliomyelitis virus from a pooled specimen of feces from 6 patients with nonparalytic poliomyelitis in Akron, Ohio, in 1947, and from another pooled specimen collected in Winston-Salem, North Carolina, in 1948. In addition, they were able to isolate the virus from the sewage of 6 cities in areas where the virus had been isolated from patients. Furthermore, the new agent was isolated from flies trapped in at least two of the same areas. A number of batches of flies collected during the epidemic of poliomyelitis that occurred in Texas in 1948 were also studied. Some of these yielded the new virus alone, others yielded only the poliomyelitis virus, and still others yielded both viruses.

The findings of the Yale workers indicate that the virus of Dalldorf and Sickles was widespread in this country in 1948 and possibly also in 1947. It is not yet entirely clear whether this is really a new virus that has made its first appearance as a human pathogen during recent years or whether it has been a factor in earlier outbreaks of paralytic infections in this country and elsewhere. The answer to this and to many other epidemiologic questions should be forthcoming as more of the stores of materials collected by these and many other workers on poliomyelitis are restudied. Further investigation should also indicate whether the epidemiology of the disease caused by the new virus is the same as that of poliomyelitis or whether it differs in such factors as seasonal distribution and the types of persons affected. The findings to date suggest that both viruses have similar epidemiologic features.

Although all the patients from whom the Yale workers isolated the strains of the new virus had nonparalytic cases, the original observations of Dalldorf and Sickles suggest that the disease caused by the new agent is not innocuous. Both their patients had definite muscular paralysis, and in one on them some of the paralysis was still present after

seven months. It is also not yet clear how often this new virus will be discovered in clinical cases with paralysis. It is evident that the new virus has been found in areas and during periods in which paralytic poliomyelitis has been prevalent, but it remains to be seen how often it will be isolated in areas free of poliomyelitis and at times when this virus is not usually to be expected. The full clinical implications of these findings are therefore not yet evident. It is already apparent, however, that the diagnosis of poliomyelitis even during epidemics has now become further complicated in that infections with this new virus will have to be considered both in paralytic and in nonparalytic infections.

The spinal fluid in 9 out of 11 patients in whom infections with the new virus was demonstrated in New Haven showed a pleocytosis. The total number of leukocytes ranged from 27 to 600 per cubic millimeter, with 27 to 95 per cent mononuclear cells. There was a patient, however, from whom the virus was isolated and whose spinal fluid showed only 3 cells. Further correlations of both clinical and laboratory findings in patients with proved infections with this new agent and with the poliomyelitis virus are also needed to determine to what extent the two diseases, in both the paralytic and the nonparalytic forms, can be distinguished on the basis of simple clinical and laboratory findings. The recent observations indicate that, like the poliomyelitis virus, the new agent may produce fever without any specific meningeal or muscular symptoms. Infections with the new virus must therefore be included in the differential diagnosis of acute cases of "fever of unknown origin."

At the present time the demonstration of infections with the new virus of Dalldorf and Sickles is still a task for the few laboratories engaged in virus research. It is hoped that with further developments, less elaborate methods may be worked out that could be more readily applied in the usual hospital bacteriologic and serologic laboratories.

NEW VIRUS FROM DISEASES RESEMBLING POLIOMYELITIS

EARLY last summer Dalldorf and Sickles,¹ of the Division of Laboratories and Research of the New York State Department of Health in Albany, reported the isolation of a filtrable agent from the feces of 2 patients with muscular paralysis. These cases were observed during a small outbreak of poliomyelitis in upstate New York in August, 1947. The virus was distinct from that of poliomyelitis in that it could be isolated only by intracerebral inoculation of suckling mice or hamsters, but monkeys were not susceptible. The lesions produced consisted of widespread degeneration of the skeletal muscles, without any apparent lesions in the central nervous system or the large peripheral nerves.

The properties of this agent were different from those of any other known viruses. Furthermore,

since it was recovered from patients with paralysis during a time when poliomyelitis was occurring to some extent in several areas of the country, it became a matter of considerable importance to learn more about its prevalence and its relation to clinical poliomyelitis. These workers, therefore, published their preliminary observations with the hope that other investigators would search for this agent and that some of them might perhaps have an opportunity to study the muscles in fatal cases of paralytic disease.

The first confirmation and extension of the findings of Dalldorf and Sickles has recently been published by Melnick, Shaw and Curnen,² of Yale University School of Medicine. The New Haven workers obtained a virus from the feces of 5 out of 13 patients with illnesses that resembled those of nonparalytic poliomyelitis or the so-called aseptic meningitis and from 2 additional patients with diagnoses of "fever of unknown origin." All their cases occurred in Connecticut and in Rhode Island during the summer and fall of 1948. They were also able to demonstrate neutralizing antibodies in the convalescent serums of all the 7 patients from whose feces the virus was isolated and in 5 additional patients with nonparalytic illness in whom attempts to isolate a virus were unsuccessful.

The properties of the virus obtained by the New Haven workers were the same as those of the agent isolated in Albany. The Yale workers were also able to demonstrate inapparent infection in chimpanzees after oral administration of the virus by recovering the virus from the nasopharynx and feces of these animals and also by proving the development of neutralizing antibodies for the new agent. In addition, one of the New Haven workers developed an accidental infection, which was characterized by fever of eight days' duration and a minimum of stiffness of the back, but no definite central-nervous-system symptoms. The new virus was recovered from the nasopharynx and feces of this worker, and neutralizing antibodies for the agent developed in his serum in increasing titer during convalescence.

Melnick and his associates extended their observations by a study of samples of feces that they had collected in previous outbreaks in different

in particular the conditioned-reflex treatment of chronic alcohol addiction as it is carried out at the Washingtonian Hospital in Boston

The conditioned-reflex treatment, at present the most promising form of therapy for alcoholism, was first reported in England in 1930. Apomorphine was the drug used in these early experiences, and an estimated success of 35 per cent was attained. In this country the Shadel Sanitarium in Seattle, Washington, first reported nearly a decade ago a considerable number of patients treated with the conditioned reflex. A 78 per cent solution of emetine was used, and 64.3 per cent total abstinence was claimed as a result. A further report from this institution was published a year ago in the *Journal*¹

At the Washingtonian Hospital, where the conditioned reflex was instituted seven years ago, a slightly modified technic has been adopted, supplemented by "methodic psychotherapy and part-time hospitalization and manipulation of the patient's environment."

Emetine is a drug not without its disadvantages, as is indicated by Thimann and has been pointed out by Kattwinkel² in his report of a case treated with emetine, with a fatal outcome. It lowers the blood pressure and in excessive doses causes arrest of the heart in diastole. The nausea induced by it may be accompanied by diarrhea, and it may be followed by muscular pain and weakness.

In its effects on the cardiovascular system lie the chief objections to emetine, Thimann reporting that 5 of the 282 patients in his series had cardiovascular manifestations, with 2 deaths. The death reported in detail occurred in a patient who flagrantly disregarded instructions.

The precautions that should be taken to prevent untoward reactions are listed by Thimann and have been referred to editorially in these columns.³ If due consideration is given to them, emetine may be employed with safety, although the search for a less toxic substitute continues.

BOSTON'S CHEST X-RAY PROGRAM

Boston, following the precedent established by various other large cities of the country, is about to launch an intensive chest x-ray program. The campaign will start on September 21 and continue until January 14; its goal is to obtain a chest x-ray examination, if possible, of every person of fifteen years of age or over who lives, works or transacts business in the city.

The younger age group is excluded from the program because of its much lower incidence of tuberculosis and because of other screening methods that are more effective than mass x-ray study—such as tuberculin testing, and case finding as a result of the adult program.

The program will be conducted under the auspices of the Boston Health Foundation, Incorporated, an organization made up of the vital health and welfare agencies of the city, which have united at this time for this specific purpose. A far-reaching system of committees has been devised, each with its particular area of responsibility. Not the least important among them is the medical committee, under the chairmanship of Dr. Dwight O'Hara, which is further divided into subcommittees for the interpretation of the program to physicians, for the supervision of and the proper referral of positive cases, and for the review of those cases that require it.

Suitable personnel and twenty mobile x-ray units are being loaned by the United States Public Health Service for the program, and these will operate, area by area, in twenty health districts established as such for the occasion. Persons with normal chest x-ray films will be promptly notified of the fact by mail, those showing any suspicion of active tuberculosis, cardiovascular disease or other pathologic conditions will be referred to their physicians, and their physicians will be so notified.

Boston, with a tuberculosis death rate in 1948 of 56.1 per 100,000 population labors under the distinction of a rate nearly twice that of the country as a whole. The program that is about to start will be of great value in correcting this situation. Of the greatest value in furthering the enterprise will be the co-operation of the medical profession in the best New England tradition of service.

"REVERENCE FOR LIFE"

AMERICA has entertained briefly on his first visit to its shores one of the world's foremost if hitherto little known physicians. Albert Schweitzer, now nearly seventy-five years of age, the son of an evangelical pastor of Alsace, has excelled in a half dozen of life's pursuits where it is given to most men to participate in only one or two.

A preacher, writer, teacher, philosopher and musician, the world's greatest interpreter of Bach, Schweitzer, when the time came, turned his back, upon the exploitation of these accomplishments, renounced the material rewards of his genius and became a medical missionary in Equatorial Africa.

Schweitzer's character, so far as it is readily definable, is revealed in the titles of his works. *The Religious Philosophy of Kant* was published when he was 24, three years after he had determined that he would consider himself justified in living until he was 30 for science and art, "in order to devote myself from that time forward to the direct service of humanity." In 1903 he began *The Quest of the Historical Jesus*. His biography of Bach is the standard text on the life of that musician, but his autobiography, *Out of My Life and Thought* remains his best known work. *The Philosophy of Civilization* will be published this fall.

Like many who have attained their goal less completely, if no less humbly, Schweitzer came early to the conclusion that for him true happiness could be achieved only through a life of self-sacrificing service to others. To that goal he would channel his brilliant attainments, after he had brought them to maturity.

Still earlier he had adopted his own secret prayer to "protect and bless all things that have breath, guard them from all evil, and let them sleep in peace." He tells later in his autobiography, as quoted by Sperry* in these pages, how the definition of this belief finally came to him.

Journeying up the river toward his hospital he was searching in his mind for some basic ethical principle, but fruitlessly. And then

Late on the third day at the very moment we were making our way through a herd of hippo-

potamuses, there flashed upon my mind, un-foreseen and unsought, the phrase "Reverence for life." For all life

This was the essence of the belief that had moved him, at 21, to continue his brilliant career in music and in preaching for only ten years more and then to study medicine and give his life wholly to others. It was the credo that brought the ultimate happiness of contentment to his mind, previously troubled despite his intellectual achievements and material success, the abnegation that always must motivate the priest or the missionary whether in foreign fields or in areas of service nearer home.

This same reverence for life and willingness for sacrifice in its behalf provide the basic material in the character of the true physician wherever his course may lie.

It is of little moment whether Schweitzer's decision was partly intellectual or wholly emotional or whether the services that he has performed in darkest Africa, comparable to those of Grenfell in Labrador, might have reaped a more productive harvest in some more fruitful area. All life, according to his uncompromising standards, must be revered and consequently preserved and strengthened and upheld.

DEMON RUM

THE fact that the uncertainties of life in a complex world lend added attraction to the offerings of the neighborhood package store accounts largely for man's eager resort to alcoholic beverages. In peaceful times as well as in disturbed ones, however, in simple as in complicated surroundings, thinking man, so far the supreme product of nature's biologic efforts, still finds it necessary to bypass with the help of alcohol the results of his ability to reason.

Some persons are able to use alcohol in this way to a limited degree and remain in general control of their activities, others—and the number is increasing—become slaves to the habit that they have acquired. Whatever the original cause of their addiction and whether or not it still persists, the addiction has with them become in itself a disease that requires treatment.

The two articles by Thimann, published a week ago and in the present issue of the *Journal*, discuss

*Sperry, W. L. Moral problems in practice of medicine. *New Eng J Med* 239:985-990, 1948.

in particular the conditioned-reflex treatment of chronic alcohol addiction as it is carried out at the Washingtonian Hospital in Boston

The conditioned-reflex treatment, at present the most promising form of therapy for alcoholism, was first reported in England in 1930. DEATHS

BERNHARDT — Henry M Bernhardt, M.D., of Arlington, died on August 31. He was in his forty-first year.

Dr Bernhardt received his degree from Boston University School of Medicine in 1935. He was physician for the Massachusetts Institute of Technology and Phillips Academy, Andover, and was a member of the New England Ophthalmological Society.

His widow, a son, a brother and a sister survive.

SCUDDER — Charles L Scudder, M.D., of Brookline, died on August 19. He was in his ninetieth year.

Dr Scudder received his degree from Harvard Medical School in 1888. He was a consulting surgeon at the Massachusetts General Hospital and was a fellow of the American College of Surgeons and the American Surgical Association and a member of the Society of Clinical Surgery and the New England Surgical Society.

A son and a daughter survive.

WASHBURN — Frederic A Washburn, M.D., of Boston, died on August 20. He was in his eighty-first year.

Dr Washburn received his degree from Harvard Medical School in 1896. He was formerly superintendent of the Massachusetts General Hospital and founded the Baker Memorial Hospital. He was director of the Massachusetts Eye and Ear Infirmary from 1915 to 1934 and was appointed commissioner of institutions in Massachusetts in 1934. He was a fellow of the American Medical Association.

His widow survives.

WILDER — Ella A Wilder, M.D., of Middletown, Connecticut, died on July 20. She was in her fifty-third year.

Dr Wilder received her degree from Boston University School of Medicine in 1923. She was a member of the New England Obstetrical and Gynecological Society and a fellow of the American Medical Association.

Her mother survives.

CORRESPONDENCE

INCURABLE READER

To the Editor Noticing the review of Dr Ronchese's book on *Occupational Marks and Other Physical Signs*, I was reminded of our old friend Dr Maurice Richardson. He was constantly urging us to observe. I remember one day he was questioning an unknown patient and asked, "Are you a steam or gas fitter?" Astonishment showed on the man's face as it did on the faces of the students. Dr Richardson smiled and pointed to a faint tattooed scar on the man's nose, shaped like a new moon.

I think this is the fifty-fifth or fifty-sixth continuous year that I have had the *Journal* and perused it with pleasure and profit — an outstanding journal.

PHILIP C MEANS, M.D.

Chula Vista, California

SEMANTICS

To the Editor I have just read your editorial "Essentially Useless" in the July 14 issue of the *Journal*, in which you rightfully call attention to "uncritical use of the language." I should like to point out the consistent use of the word "regime" in indicating in your journal a program of therapy. I have also noted in another of your editorials ("Medical Practice in Great Britain" in the *Journal* of February 3) the use of "regimen" as a system of government. The following definitions are given in my *Funk and Wagnalls Desk Dictionary*.

Regime, n. System of government or administration, social system.

Regimen, n. 1. A systematized course of living, as to food, clothing, etc. 2. Government, control.

It seems from the above that "regimen" applies either to government or to therapy, but that "regime" should be limited to use in referring to government.

HERBERT N JACOBS, M.D.

San Francisco

Note: Webster's *International Dictionary* (1948) is less scrupulous in the definition of regime. 1. Mode or system of rule or management, character of government or of the social system. 2. Hydraulic. 3. Med. Regimen — Ed.

ACROMIOCLAVICULAR DISLOCATION

To the Editor A perusal of Dr Boardman Marsh Bosworth's paper, "Complete Acromioclavicular Dislocation," which appeared in the August 11 issue of the *Journal*, prompts the following observations

Complete dislocation at the acromioclavicular joint is not invariably associated with avulsion of the coracoid and trapezoid ligaments, or as Dr Bosworth calls them, the "coracoclavicular ligament." This statement is based on the work of Poirier and Rieffel, in their study entitled "Mécanisme des luxations sus-acromiales de la clavicule leur traitement par la suture assidue" (*Arch gén de méd* 1 396-422, 1891), and of Cadanot, in his article "The Treatment of Dislocations and Fractures of the Outer End of the Clavicle" (*Internat Clin* 27 145-169, 1917). It has recently been confirmed by Urst in a paper entitled "Complete Dislocation of the Acromioclavicular Joint" (*J Bone & Joint Surg* 28 813-837, 1946). I was associated with Dr Urst during a part of the time he was carrying out his studies on this subject and can confirm his conclusions. On the basis of numerous dissections of fresh material and observations at the operating table, Urst states "When these structures (the joint capsule and attachments of the trapezius and deltoid muscles) were severed, to simulate the tearing or stretching which occurs in them with dislocation, complete dislocation of the outer end of the clavicle was possible without injury to the coracoid or trapezoid ligaments. It is true that rupture of the coracoid and trapezoid ligaments allowed greater displacement of the clavicle, but the picture was altered quantitatively, not essentially."

Integrity of the clavicle or its associated joints is not essential for normal function of the shoulder. Fitchet, in an exhaustive study entitled "Cleidocranial Dysostosis Hereditary and familial" (*J Bone & Joint Surg* 11 838-866, 1929), found almost no evidence of impairment of function in his cases or those reported in the literature. Although it is true that in the presence of injury to the clavicle or dislocation of the acromioclavicular joint the shoulder "droops" downward and forward, there is also an upward component of force that has not generally been recognized. Gordon, in 1875, called attention to this in his book, *A Treatise on the Fractures of the Lower End of the Radius, on Fractures of the Clavicle, and on Reduction of the Recent Inward Dislocations of the Shoulder Joint* (London: J & A Churchill), and pointed out that in the absence of the strut of the clavicle the muscles of the shoulder girdle as a whole tend to force the shoulder toward the apex of the truncated cone of the thorax.

Complete dislocation of the acromioclavicular joint is not incompatible with excellent function. I recently had an opportunity of examining a professional football player, who is able to throw forward passes with great skill despite the fact that the distal end of his clavicle lies on the superior surface of his acromion even at rest. Two similar cases in college athletes have been seen in the past two years.

Motion between the clavicle and the coracoid process of the scapula is considerable and complex. This can easily be demonstrated by a simple experiment, which was repeated today and in which a healthy, twenty-eight-year-old man, who had never suffered an injury to his shoulder girdle, was placed upright facing an x-ray cassette and films were taken with the arm hanging at the side and held directly overhead. Between the former and the latter the coracoid process moved 1 inch toward the distal end of the clavicle and rotated upward an estimated 40°, and the clavicle itself rotated on its own axis upward and backward an estimated 90°.

Fixation or "suspension" between the coracoid process and the clavicle such as Dr Bosworth advocates severely must strain either the fixation apparatus or the bones involved. The effect of the fixation seems to be the same as fusion of the acromioclavicular joint, which Dr Bosworth very properly condemns. Even if care is taken to leave the proximal end of the screw loose, as Dr Bosworth recommends, limitation of motion between the coracoid and the clavicle must be marked.

A plea for conservative management of acromioclavicular joint injuries was made by Thorndike and Quigley in a paper "Injuries to the Acromioclavicular Joint. A plea for conservative treatment" (*Am J Surg* 55 250-261, 1942). The results of treatment of 138 acromioclavicular dislocations or separations of varying degree in athletes were reported. In none was operation found necessary. As Urst

pointed out, associated injury to the trapezius and deltoid muscles plays a large part in separation of the distal end of the clavicle from the acromion after an injury to the shoulder. As the integrity and tone of these injured muscles return, an apparently severe separation often changes to a trivial laxity of the joint that produces neither symptoms nor disability.

Surgery, when necessary, is usually indicated for cosmetic reasons, or for relief of pain, which may accompany the imperfect function of chronic partial dislocation. In either case simple removal of the outer end of the clavicle, as recommended by Gurd, in his report entitled "Surplus Parts of the Skeleton" (*Am J Surg* 74 705-720, 1947), has been satisfactory. For the rare patient whose livelihood depends on prompt restoration of appearance and function, a lashing operation, using strips of fascia lata, may be indicated.

T B QUIGLEY, M D

Boston, Massachusetts

Dr Quigley's letter was submitted to Dr Bosworth, who offers the following reply:

To the Editor I was delighted to read Dr Quigley's comments on my recent paper and feel complimented that he was inspired to make them. Thank you for granting me the opportunity to reply.

It may be that complete dislocation can occur without tearing of the coracoclavicular ligaments. I have not seen this happen.

I believe that whether or not integrity of the acromioclavicular joint is essential for normal function is a matter of opinion and depends upon one's definition of "normal."

I admit that complete acromioclavicular dislocation may not be incompatible with excellent function, but, if it occurs, it must be the exception rather than the rule.

Dr Quigley is correct in stating that motion between the clavicle and the coracoid process is complex. Whether or not it is "considerable" again depends upon definition of that word.

Dr Quigley writes that of 138 acromioclavicular dislocations reported by him in 1942 none required operation. I congratulate him! However, he does not indicate how many of these were complete dislocations. This is the very crux of the problem, since treatment and prognosis will vary according to whether the joint separation is *partial* or *complete*. Any discussion of the subject that fails clearly to distinguish between the two merely confuses the reader. May I point out that the paper in question was expressly limited to *complete* dislocations.

Whether or not the insertion of a screw in the manner I describe is called "fixation" or "suspension" is beside the point. It works.

BOARDMAN MARSH BOSWORTH, M D

Bronxville, New York

A QUESTION OF CONSISTENCY

To the Editor I am somewhat confused by an apparent basic inconsistency between your interesting editorial on the Danish program for criminal psychopaths in the July 7 issue of the *Journal* and your fine editorial comment in the July 14 issue concerning Dr Alexander's sobering revelations of medical atrocities under Hitler.

The former editorial endorses the policy of the Danish program and refers with apparent approval to castration as a condition of release of sex offenders, "just as numbers of the inmates of mental-deficiency institutions have been sterilized before release."

On the other hand, the July 14 editorial wholly endorses Dr Alexander's position, a major tenet of which is the fact that medical practices of exactly this sort may lead to that situation in which criteria for sterilization reflect political as well as medical motivations.

It is difficult for me to reconcile the Danish position with the warnings expressed by Dr Alexander. I should appreciate the comments of the editors on the points raised in the two editorials cited.

I take this opportunity, in passing, of commending the *Journal* for its continued policy of fairness and open-mindedness, which has made it one of the few medical organs that

have maintained objectivity in the sociologic as well as the scientific aspects of medicine

E. RICHARD WEINERMAN, M.D.

Visiting Associate Professor of Medical Economics

University of California School of Public Health
Berkeley, California

Note The Herstedvester editorial referred to by Dr. Weinerman committed the *Journal* to the extent of saying that the penal code of Denmark had much to recommend it. The editors did not thereby intend to commit themselves to either approval or disapproval of the particular point that Dr. Weinerman has stressed—that of castration as a condition of release of sex offenders.

The address by Dean Sperry published in the *Journal* for December 23, 1948, is recalled, in which he states that often the choice between the right course and the wrong one is not between black and white but between two shades of gray, both of which have points that recommend them.—Ed

BOOK REVIEWS

Textbook for Almoners. By Dorothy Manchec, almoner, St. Mary's Hospital, London. With a foreword by Sir Alfred B. Howitt, C.V.O., M.D., president, Institute of Almoners. 8°, cloth, 466 pp., with 49 diagrams and drawings. Baltimore: Williams and Wilkins Company, 1947. \$7.50.

In ancient times an almoner was the keeper of the purse, although at St. Bartholomew's Hospital in London the "Almoners," later called the House Committee, originally had the duty of interviewing all patients and admitting them to the hospital at discretion. Today the almoners in England are the medical social workers, as they are known in the United States. Sir Charles Loch, the secretary of the Family Welfare Association, formerly the Charity Organization Society, was the founder of the modern almoning profession. As early as 1885 he became interested in social work in hospitals, and in 1894 he succeeded in interesting his organization in the matter, in 1895 Miss Mary Stewart, a secretary of the Charity Organization Society, was appointed to the position of almoner at the Royal Free Hospital, the first almoner to be appointed in England. Her duties as laid down by the hospital board were to prevent any abuse of the hospital by persons able to pay for medical treatment, and to refer destitute patients to the proper authorities. It is only within recent years that hospitals in the United States have taken steps to control this abuse. The movement has steadily progressed until today in England there is a well established profession of almoning with its governing institute, composed of management and labor, broadly speaking, and its own hospital-almoners' association. In October, 1945 the *Interim Report of the Social and Preventive Medicine Committee of the Royal College of Physicians* was published. It confines the functions of the almoners to medical social work. The Institute stated that the chief function of an almoner shall be medicosocial work in its various aspects. They may assume as required certain administrative responsibilities, such as checking patients' ability to pay fees.

This book constitutes a valuable document concerning the development of medical social work in England. The text is divided into four parts: origin and growth of the almoner service, social legislation, financial assistance, and social aspects of disease. In the last part are discussed the various subdivisions of the practice of medicine.

The text was printed in Great Britain and is well done with a good type on a light, soft non-glare paper. Although the book is dated 1947, it was not distributed until recently in the United States. Miss Manchec is the author of two previous small books: *Social Service in a General Hospital* and *Social Service in the Clinic for Venereal Disease*. Although the text is based on London experience and on British legislation and regulations, the book should be in all collections on social service work, both medical and general.

Medicine throughout Antiquity. By Benjamin L. Gordon, M.D. With a foreword by Dr. Max Neuburger. 8°, cloth, 818 pp., with 157 illustrations. Philadelphia: F. A. Davis Company, 1949. \$6.00.

Dr. Gordon has traced the history of early medicine from the beginning of man, reputed to be about half a million years B.C., to the end of the Greco-Roman period, terminating

with the fall of Rome in 476 A.D. He has compiled from all available widely recognized sources the facts pertinent to his subject. The work has been divided into two main parts: the prehistoric and protohistoric periods, and the Greco-Roman period. This last period is susceptible to a fuller exposition because of the extensive literature on it. The first period, the prehistoric, begins with the first appearance of man and ends when history began to be recorded, here one must depend on archaeology, paleology and palaeopathology for facts revealed by human fossils, cave and stone drawings and paintings, and on primitive instruments. In the protohistoric period the facts are drawn from such documents as the code of Hammurabi, the Old Testament of the Bible and the works of Homer, this period extended until the rise of the Ionian school of philosophy about 600 B.C. The second period begins with Thales of Miletus, of the Grecian school of philosophers. In the first division of his work the author includes material on paleology and evolution, on the primitive concepts of disease and death, and on the early concepts of nature, and on the Ionian and Athenian schools of philosophy as necessary for an understanding of early medicine. In this chapter on early man one notices the omission of Osborn's great work, *Men of the Old Stone Age*. Likewise, the outstanding work of Hovorka and Kronfeld, *Folkmedicine*, seems to have been missed. After the general chapters the medicine of the various races is discussed, beginning with the Assyrians and Babylonians and including the ancient Egyptians, Hebrew medicine, Persians, Hindus, Japanese and the prehistoric American Indians. The last two chapters of the book are on Talmudic medicine, and they would better have been placed with the one on Hebrew medicine. Many persons confuse the meaning of the words Hebrew and Jew. Modern scholars limit the word Hebrew to the language and refer to the race as the Jews. There is a looseness in dating Jewish medicine. In the opening paragraphs on ancient "Hebrew medicine" the time of Abraham is noted in one place as 2000 B.C. and in another as 2500 B.C. Likewise, the period of the Talmud is not dated. The second section of the work is divided into two parts on Grecian and Roman medicine, beginning with chapters on Aesculapian and Homeric medicine, on the influence of philosophy on medicine and on the Ionian and Eleatic schools of philosophy and on the medical philosophers and practitioners. The whole subject is covered from Hippocrates to the empirics. The part on Roman medicine considers the period from the Methodic school to Galen. The vivid description by Ovid of the pestilence that raged in Rome during the period of his life, 43 B.C. to 17 A.D., is given in an English translation. It is noted that the famous description by Thucydides of the plague at Athens is not mentioned. There are a number of typographic errors in the text, such as "Calumella" for "Columella" and "Gellius" for "Aulus Gellius." The various chapters are documented with lists of references and notes to passages in the text. The references in many cases are poorly cited, omitting edition, place and date and, in some cases, the title. There is a long index, but it does not contain all the names in the text or references. The type, printing and illustrations are excellent, but the coated paper makes the volume too heavy for continuous reading. The material on Jewish medicine is valuable because it is in English and easier to use than the monumental work of Preuss, *Biblisch-talmudische Medizin*. The history should be in all medical libraries and medical-history collections.

Hindu Medicine. By Henry R. Zimmer, Ph.D. Edited with a foreword and preface by Ludwig Edelstein, Ph.D. 12°, cloth, 203 pp. Baltimore: Johns Hopkins Press, 1948.

The late Professor Zimmer, in 1940, delivered the seventh course of the Hideyo Noguchi lectures at Johns Hopkins Institute of the History of Medicine. He was preparing the material for publication, after making considerable revision, enlargement and rearrangement, when he died suddenly early in 1943. He had completed the first lecture and the greater part of the second lecture, but the third lecture was represented by a great deal of fragmentary memoranda. It was quite evident from a study of the material that the work, as originally planned, could not be published. Professor Edelstein and Mrs. Zimmer considered the matter and finally decided to print the first two lectures from the manuscript without alteration. The third lecture represents a reconstruction, as far as possible, of the author's ideas and concepts of

certain diseases and cures and two appendixes, comprising the translation of the tables of contents of the *Susruta-Samhita* and the *Encyclopedia of the Elephant Man*. This reconstruction, which was made by Dr Edelstein, is contained in a long preface of fifty-six pages. Professor Zimmer had no idea of competing with Jolly's scholarly work on Indian medicine contained in the *Encyclopedia of Indo-Aryan Research*, Vol 3 Strassburg, 1901. He was endeavoring to interpret Hindu culture so as to understand its meaning in its own terms and to ascertain its value for men today. The two lectures printed are entitled "Medical Tradition and the Hindu Physician" and "The Human Body: Its forces and resources." The text is concluded with notes to the introduction and the lectures, and an index of passages from the classical Hindu texts. The small volume is well published but lacks an index to the contents. It should be in all medical-history collections.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Biological Reactions Caused by Electric Currents and by X-Rays. A theoretical study of the phenomena of excitation in the nerve by different electric currents and of the biological reactions caused by X-Rays, both based upon a common principle. By J. Th. van der Werff, M.D., D.Sc. 8°, cloth, 203 pp., with 38 illustrations. New York: Elsevier Publishing Company, Incorporated, 1948. \$5.00.

This monograph is a highly technical presentation of its subject, written for physiologists and radiologists. Although the study is biologic, the author has made an extensive use of mathematics. However, two of the highly technical parts are concluded with chapters entitled "Summary" and "Conclusions," in which all the mathematics, except the fundamental equations, have been left out. The text is divided into three parts: the first consists of a general introduction and essentials (including a hypothetical equation of metabolism). In this part the author points out that the phenomena of excitation caused by electric currents, especially those of excitation of the nerve, and the biologic reactions caused by x-rays are analogous to such an extent that it is highly probable that they may be explained from a common principle. Likewise in this part, the author has tried to formulate this principle but has had to resort to bigger mathematics without which the formulation could not have been made. The second part discusses the electric excitation of the nerve and the third, biologic relations caused by x and gamma rays. The pertinent literature is referred to throughout the text and instead of a regular bibliography, there is a list of the authors mentioned and the sources of their articles. There are also author and subject indexes. The book is well published in every way. The comparatively high price for such a small volume is justified by the great number of intricate mathematical formulas. The volume should be in all collections on radiology and physiology.

Diseases of the Ear, Nose, and Throat. By Douglas G. Carruthers, M.B., Ch.M. (Sydney) consulting ear nose and throat surgeon, Canterbury District Memorial Hospital, Sydney. Second edition. 8°, cloth, 344 pp., with 140 illustrations. Baltimore: Williams and Wilkins Company, 1948. \$7.00.

The first edition of this small textbook for students and general practitioners was published in Sydney in 1943. This second edition has been revised and the use of penicillin and the sulfonamides has been included as well as the newest form of treatment for tropical otitis externa. The technique for tonsillectomy is given in detail. There is a "pharmaceutical" index, comprising standard recipes, and also an index of subjects. The text was printed in Great Britain and is well done. The publication on the whole is excellent.

Reprints from the Oxford-Loose-Leaf Medicine. By Walter C. Alvarez and others. 8°, paper. New York: Oxford University Press, Incorporated, 1948. Not for sale.

This collection of reprints comprises twenty-one articles taken from the latest edition of the *Oxford System of Medicine*. They cover the whole field of medicine and are supplied only to subscribers to the complete work and are not for sale. They are valuable to libraries because they offer in a single form various worthwhile articles that may be lent, and the bound volumes of the system may thus be kept available for reference.

Veterans Administration Technical Bulletin, Vol. I 1946 and 1947. 4° cloth, 240 pp. Washington, 1948. Vol. II, 1948. 4°, cloth, 168 pp. Washington, 1949.

These two volumes for 1946-1948 contain thirty-six articles of a clinical character covering the whole field of practical medicine. They are intended primarily for the staff of the Veterans Administration. They are produced in an excellent manner by offset printing and are substantially and well bound. They should be in all reference medical libraries.

Surgery of the Hand. By Sterling Bunnell, M.D., consultant in hand surgery to the Surgeon General and licentiate of American Board of General Surgery and Plastic Surgery. First edition. 4°, cloth, 930 pp., with 779 illustrations. Philadelphia: J. B. Lippincott Company, 1948. \$16.00.

This second edition of a standard special work has been revised to bring its contents up to date since the publication of the first edition in 1944. Considerable material has been added, mostly to the chapters on reconstruction injuries, infection and tumors. Lists of references are appended to the various chapters. The book is profusely and well illustrated. There is a good index. The volume is recommended for all medical libraries and it should prove valuable to surgeons interested in the hand.

Cardiology. By William Evans, M.D., D.Sc., F.R.C.P., physician to the cardiac department of the London Hospital, physician to outpatients of the National Heart Hospital and consulting cardiologist to the Royal Navy. 8°, cloth, 330 pp., with 269 illustrations and 15 tables. New York: Paul B. Hoeber, Incorporated, 1948. \$7.50.

This condensed treatise is intended for the medical student who desires a concise book to prepare him for his final examinations. The work is based on a series of lectures given to postgraduate students at the London Hospital. The material is well organized. The text was printed in Great Britain with a good type. There is considerable waste of paper in the make-up of the index. It is surprising how many British books are being imported in pages into the United States and then bound and distributed by various publishers, in preference to promotion of works by native authors. Of course this practice is helping Great Britain in its export program.

Cancer of the Esophagus and Gastric Cardia. Edited by George T. Pack, M.D., clinical professor of surgery, New York Medical College and attending surgeon, Memorial Hospital for Cancer and Allied Diseases. 8°, cloth, 192 pp., with illustrations. St. Louis: C. V. Mosby Company, 1949. \$5.00.

This monograph is a reprint of a symposium originally published in *Surgery* for June 1948. Eighteen specialists presented eleven articles, three of which discuss the transthoracic and transdiaphragmatic methods. The publishing is excellent. The book should prove valuable to surgeons interested in the subject, and libraries could well substitute it for the bound volume of the periodical.

Shock And allied forms of failure of the circulation. By H. A. Davis, M.D., C.M., associate professor of surgery and director, Division of Surgery, Graduate School of Medicine, College of Medical Evangelists, Los Angeles Division, senior attending surgeon, Los Angeles County General Hospital and White Memorial Hospital and visiting surgeon, Cedars of Lebanon Hospital and California Hospital. 8°, cloth, 595 pp., with 55 illustrations. New York: Grune and Stratton, 1949. \$12.00.

This comprehensive monograph considers shock in all its varying aspects. Beginning with a historical introduction including classification, the text proceeds from physiology,

have maintained objectivity in the sociologic as well as the scientific aspects of medicine.

Modern scholars limit the word Hebrew to the language and refer to the race as the Jews. There is a looseness in dating Jewish medicine. In the opening paragraphs on ancient "Hebrew medicine" the time of Abraham is noted in one place as 2000 B.C. and in another as 2500 B.C. Likewise, the period of the Talmud is not dated. The second section of the work is divided into two parts on Grecian and Roman medicine, beginning with chapters on Aesculapian and Homeric medicine, on the influence of philosophy on medicine and on the Ionian and Eleatic schools of philosophy and on the medical philosophers and practitioners. The whole subject is covered from Hippocrates to the empires. The part on Roman medicine considers the period from the Methodic school to Galen. The vivid description by Ovid of the pestilence that raged in Rome during the period of his life, 43 B.C. to 17 A.D., is given in an English translation. It is noted that the famous description by Thucydides of the plague at Athens is not mentioned. There are a number of typographic errors in the text, such as "Calumella" for "Columella" and "Gellius" for "Aulus Gellius." The various chapters are documented with lists of references and notes to passages in the text. The references in many cases are poorly cited, omitting edition, place and date and, in some cases, the title. There is a lone index, but it does not contain all the names in the text or references. The type, printing and illustrations are excellent but the coated paper makes the volume too heavy for continuous reading. The material on Jewish medicine is valuable because it is in English and easier to use than the monumental work of Preuss, *Biblisch-talmudische Medizin*. The history should be in all medical libraries and medical-history collections.

Hindu Medicine. By Henry R. Zimmer, Ph.D. Edited with a foreword and preface by Ludwig Edelstein, Ph.D. 12°, cloth, 203 pp. Baltimore: Johns Hopkins Press, 1948.

The late Professor Zimmer, in 1940, delivered the seventh course of the Hideo Noguchi lectures at Johns Hopkins Institute of the History of Medicine. He was preparing the material for publication, after making considerable revision, enlargement and rearrangement, when he died suddenly in 1943. He had completed the first lecture and the early part of the second lecture, but the third lecture was greater part of the second lecture, but the third lecture was represented by a great deal of fragmentary memoranda. It was quite evident from a study of the material that the work, originally planned, could not be published. Professor Edelstein and Mrs. Zimmer considered the matter and finally decided to print the first two lectures from the manuscript without alteration. The third lecture represents a reconstruction, as far as possible, of the author's ideas and concepts of

certain diseases and cures and two appendixes, comprising the translation of the tables of contents of the *Susruta-Samhita* and the *Encyclopedia of the Elephant Man*. This reconstruction, which was made by Dr Edelstein, is contained in a long preface of fifty-six pages. Professor Zimmer had no idea of competing with Jolly's scholarly work on Indian medicine contained in the *Encyclopedia of Indo-Aryan Research*, Vol 3 Strassburg, 1901. He was endeavoring to interpret Hindu culture so as to understand its meaning in its own terms and to ascertain its value for men today. The two lectures printed are entitled "Medical Tradition and the Hindu Physician" and "The Human Body: Its forces and resources." The text is concluded with notes to the introduction and the lectures, and an index of passages from the classical Hindu texts. The small volume is well published but lacks an index to the contents. It should be in all medical-history collections.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Biological Reactions Caused by Electric Currents and by X-Rays. A theoretical study of the phenomena of excitation in the nerve by different electric currents and of the biological reactions caused by X-Rays, both based upon a common principle. By J. Th. van der Werff, M.D., D.Sc. 8°, cloth, 203 pp., with 38 illustrations. New York: Elsevier Publishing Company, Incorporated, 1948. \$5.00.

This monograph is a highly technical presentation of its subject, written for physiologists and radiologists. Although the study is biologic, the author has made an extensive use of mathematics. However, two of the highly technical parts are concluded with chapters entitled "Summary" and "Conclusions," in which all the mathematics, except the fundamental equations, have been left out. The text is divided into three parts: the first consists of a general introduction and essentials (including a hypothetical equation of metabolism). In this part the author points out that the phenomena of excitation caused by electric currents, especially those of excitation of the nerve, and the biologic reactions caused by x-rays are analogous to such an extent that it is highly probable that they may be explained from a common principle. Likewise, in this part, the author has tried to formulate this principle but has had to resort to higher mathematics without which the formulation could not have been made. The second part discusses the electric excitation of the nerve and the third, biologic relations caused by x and gamma rays. The pertinent literature is referred to throughout the text and instead of a regular bibliography, there is a list of the authors mentioned and the sources of their articles. There are also author and subject indexes. The book is well published in every way. The comparatively high price for such a small volume is justified by the great number of intricate mathematical formulas. The volume should be in all collections on radiology and physiology.

Diseases of the Ear, Nose, and Throat. By Douglas G. Carruthers, M.B., Ch.M. (Sydney) consulting ear, nose and throat surgeon, Canterbury District Memorial Hospital, Sydney. Second edition. 8°, cloth, 344 pp., with 140 illustrations. Baltimore: Williams and Wilkins Company, 1948. \$7.00.

The first edition of this small textbook for students and general practitioners was published in Sydney in 1943. This second edition has been revised and the use of penicillin and the sulfonamides has been included as well as the newest form of treatment for tropical otitis externa. The technique for tonsillectomy is given in detail. There is a 'pharmaceutical' index, comprising standard recipes, and also an index of subjects. The text was printed in Great Britain and is well done. The publication on the whole is excellent.

Reprints from the Oxford-Loose-Leaf Medicine. By Walter C. Alvarez and others. 8°, paper. New York: Oxford University Press, Incorporated, 1948. Not for sale.

This collection of reprints comprises twenty-one articles taken from the latest edition of the *Oxford System of Medicine*. They cover the whole field of medicine and are supplied only to subscribers to the complete work and are not for sale. They are valuable to libraries because they offer in a single form various worthwhile articles that may be lent, and the bound volumes of the system may thus be kept available for reference.

Veterans Administration Technical Bulletin, Vol 1, 1946 and 1947. 4° cloth, 240 pp. Washington, 1948. Vol II, 1948. 4°, cloth, 168 pp. Washington, 1949.

These two volumes for 1946-1948 contain thirty-six articles of a clinical character covering the whole field of practical medicine. They are intended primarily for the staff of the Veterans Administration. They are produced in an excellent manner by offset printing and are substantially and well bound. They should be in all reference medical libraries.

Surgery of the Hand. By Sterling Bunnell, M.D., consultant in hand surgery to the Surgeon General and licentiate of American Board of General Surgery and Plastic Surgery. First edition. 4°, cloth, 930 pp., with 779 illustrations. Philadelphia: J. B. Lippincott Company, 1948. \$16.00.

This second edition of a standard special work has been revised to bring its contents up to date since the publication of the first edition in 1944. Considerable material has been added mostly to the chapters on reconstruction, injuries, infection and tumors. Lists of references are appended to the various chapters. The book is profusely and well illustrated. There is a good index. The volume is recommended for all medical libraries and it should prove valuable to surgeons interested in the hand.

Cardiology. By William Evans, M.D., D.Sc., F.R.C.P., physician to the cardiac department of the London Hospital physician to outpatients of the National Heart Hospital and consulting cardiologist to the Royal Navy. 8°, cloth, 330 pp., with 269 illustrations and 15 tables. New York: Paul B. Hoeber, Incorporated, 1948. \$7.50.

This condensed treatise is intended for the medical student who desires a concise book to prepare him for his final examinations. The work is based on a series of lectures given to postgraduate students at the London Hospital. The material is well organized. The text was printed in Great Britain with a good type. There is considerable waste of paper in the make-up of the index. It is surprising how many British books are being imported in pages into the United States and then bound and distributed by various publishers, in preference to promotion of works by native authors. Of course, this practice is helping Great Britain in its export program.

Cancer of the Esophagus and Gastric Cardia. Edited by George T. Pack, M.D., clinical professor of surgery, New York Medical College and attending surgeon, Memorial Hospital for Cancer and Allied Diseases. 8°, cloth, 192 pp., with illustrations. St. Louis: C. V. Mosby Company, 1949. \$5.00.

This monograph is a reprint of a symposium originally published in *Surgery* for June, 1948. Eighteen specialists presented eleven articles, three of which discuss the transthoracic and transdiaphragmatic methods. The publishing is excellent. The book should prove valuable to surgeons interested in the subject, and libraries could well substitute it for the bound volume of the periodical.

Shock And allied forms of failure of the circulation. By H. A. Davis, M.D., Ch.M., associate professor of surgery and director, Division of Surgery, Graduate School of Medicine, College of Medical Evangelists, Los Angeles Division senior attending surgeon, Los Angeles County General Hospital and White Memorial Hospital and visiting surgeon, Cedars of Lebanon Hospital and California Hospital. 8°, cloth, 595 pp., with 55 illustrations. New York: Grune and Stratton, 1949. \$12.00.

This comprehensive monograph considers shock in all its varying aspects. Beginning with a historical introduction, including classification, the text proceeds from physiology,

have maintained objectivity in the sociologic as well as the scientific aspects of medicine

L. RICHARD WEINERMAN, M.D.

Visiting Associate Professor of Medical Economics

University of California School of Public Health
Berkeley, California

Note The Herstedvester editorial referred to by Dr. Weinerman committed the *Journal* to the extent of saying that the penal code of Denmark had much to recommend it. The editors did not thereby intend to commit themselves to either approval or disapproval of the particular point that Dr. Weinerman has stressed—that of castration as a condition of release of sex offenders.

The address by Dean Sperry published in the *Journal* for December 23, 1948, is recalled, in which he states that often the choice between the right course and the wrong one is not between black and white but between two shades of gray, both of which have points that recommend them.—Ed

BOOK REVIEWS

Textbook for Almoners. By Dorothy Manchée, almoner, St Mary's Hospital, London. With a foreword by Sir Alfred B. Howitt, C.V.O., M.D., president, Institute of Almoners. 8°, cloth, 466 pp., with 49 diagrams and drawings. Baltimore: Williams and Wilkins Company, 1947. \$7.50.

In ancient times an almoner was the keeper of the purse, although at St. Bartholomew's Hospital in London the "Almoners," later called the House Committee, originally had the duty of interviewing all patients and admitting them to the hospital at discretion. Today the almoners in England are the medical social workers, as they are known in the United States. Sir Charles Loch, the secretary of the Family Welfare Association, formerly the Charity Organization Society, was the founder of the modern almoning profession. As early as 1885 he became interested in social work in hospitals, and in 1894 he succeeded in interesting his organization in the matter, in 1895 Miss Mary Stewart, a secretary of the Charity Organization Society, was appointed to the position of almoner at the Royal Free Hospital, the first almoner to be appointed in England. Her duties as laid down by the hospital board were to prevent any abuse of the hospital by persons able to pay for medical treatment, and to refer destitute patients to the proper authorities. It is only within recent years that hospitals in the United States have taken steps to control this abuse. The movement has steadily progressed until today in England there is a well established profession of almoning with its governing institute, composed of management and labor, broadly speaking, and its own hospital-almoners' association. In October, 1945 the *Interim Report of the Social and Preventive Medicine Committee of the Royal College of Physicians* was published. It confines the functions of the almoners to medical social work. The Institute stated that the chief function of an almoner shall be medico-social work in its various aspects. They may assume as required certain administrative responsibilities, such as checking patients' ability to pay fees.

This book constitutes a valuable document concerning the development of medical social work in England. The text is divided into four parts: origin and growth of the almoner service, social legislation, financial assistance, and social aspects of disease. In the last part are discussed the various subdivisions of the practice of medicine.

The text was printed in Great Britain and is well done with a good type on a light, soft non-glare paper. Although the book is dated 1947, it was not distributed until recently in the United States. Miss Manchée is the author of two previous small books: *Social Service in a General Hospital* and *Social Service in the Clinic for Venereal Disease*. Although the text is based on London experience and on British legislation and regulations, the book should be in all collections on social service work, both medical and general.

Medicine throughout Antiquity. By Benjamin L. Gordon, M.D. With a foreword by Dr. Max Neuburger. 8°, cloth, 818 pp., with 157 illustrations. Philadelphia: F. A. Davis Company, 1949. \$6.00.

Dr. Gordon has traced the history of early medicine from the beginning of man, reputed to be about half a million years B.C., to the end of the Greco-Roman period, terminating

with the fall of Rome in 476 A.D. He has compiled from all available widely recognized sources the facts pertinent to his subject. The work has been divided into two main parts: the prehistoric and protohistoric periods, and the Greco-Roman period. This last period is susceptible to a fuller exposition because of the extensive literature on it. The first period, the prehistoric, begins with the first appearance of man and ends when history began to be recorded, here one must depend on archeology, paleology and paleopathology for facts revealed by human fossils, cave and stone drawings and paintings, and on primitive instruments. In the protohistoric period the facts are drawn from such documents as the code of Hammurabi, the Old Testament of the Bible and the works of Homer, this period extended until the rise of the Ionian school of philosophy about 600 B.C. The second period begins with Thales of Miletus, of the Grecian school of philosophers. In the first division of his work the author includes material on paleology and evolution, on the primitive concepts of disease and death, and on the early concepts of nature, and on the Ionian and Athenian schools of philosophy as necessary for an understanding of early medicine. In the chapter on early man one notices the omission of Osborn's great work, *Men of the Old Stone Age*. Likewise, the outstanding work of Hovorka and Kronfeld, *Folkmedicine*, seems to have been missed. After the general chapters the medicine of the various races is discussed, beginning with the Assyrians and Babylonians and including the ancient Egyptians, Hebrew medicine, Persians, Hindus, Japanese and the prehistoric American Indians. The last two chapters of the book are on Talmudic medicine, and they would better have been placed with the one on Hebrew medicine. Many persons confuse the meaning of the words Hebrew and Jew. Modern scholars limit the word Hebrew to the language and refer to the race as the Jews. There is a looseness in dating Jewish medicine. In the opening paragraphs on ancient "Hebrew medicine" the time of Abraham is noted in one place as 2000 B.C. and in another as 2500 B.C. Likewise, the period of the Talmud is not dated. The second section of the work is divided into two parts on Grecian and Roman medicine beginning with chapters on Aesculapian and Homeric medicine, on the influence of philosophy on medicine and on the Ionian and Eleatic schools of philosophy and on the medical philosophers and practitioners. The whole subject is covered from Hippocrates to the empirics. The part on Roman medicine considers the period from the Methodic school to Galen. The vivid description by Ovid of the pestilence that raged in Rome during the period of his life, 43 B.C. to 17 A.D., is given in an English translation. It is noted that the famous description by Thucydides of the plague at Athens is not mentioned. There are a number of typographic errors in the text, such as "Calumella" for "Columella" and "Gellius" for "Aulus Gellius." The various chapters are documented with lists of references and notes to passages in the text. The references in many cases are poorly cited, omitting edition, place and date and, in some cases, the title. There is a long index, but it does not contain all the names in the text or references. The type, printing and illustrations are excellent, but the coated paper makes the volume too heavy for continuous reading. The material on Jewish medicine is valuable because it is in English and easier to use than the monumental work of Preuss, *Biblich-talmudische Medizin*. The history should be in all medical libraries and medical-history collections.

Hindu Medicine. By Henry R. Zimmer, Ph.D. Edited with a foreword and preface by Ludwig Edelstein, Ph.D. 12°, cloth, 203 pp. Baltimore: Johns Hopkins Press, 1948.

The late Professor Zimmer, in 1940, delivered the seventh course of the Hideo Noguchi lectures at Johns Hopkins Institute of the History of Medicine. He was preparing the material for publication, after making considerable revision, enlargement and rearrangement, when he died suddenly in 1943. He had completed the first lecture and the greater part of the second lecture, but the third lecture was represented by a great deal of fragmentary memoranda. It was quite evident from a study of the material that the work, originally planned, could not be published. Professor Edelstein and Mrs. Zimmer considered the matter and finally decided to print the first two lectures from the manuscript without alteration. The third lecture represents a reconstruction, as far as possible, of the author's ideas and concepts of

certain diseases and cures and two appendixes, comprising the translation of the tables of contents of the *Susruta-Samhita* and the *Encyclopedia of the Elephant Man*. This reconstruction, which was made by Dr. Edelstein, is contained in a long preface of fifty-six pages. Professor Zimmer had no idea of competing with Jolly's scholarly work on Indian medicine, contained in the *Encyclopedia of Indo-Aryan Research*, Vol. 3, Strassburg, 1901. He was endeavoring to interpret Hindu culture so as to understand its meaning in its own terms and to ascertain its value for men today. The two lectures printed are entitled "Medical Tradition and the Hindu Physician" and "The Human Body: Its forces and resources." The text is concluded with notes to the introduction and the lectures, and an index of passages from the classical Hindu texts. The small volume is well published but lacks an index to the contents. It should be in all medical-history collections.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Biological Reactions Caused by Electric Currents and by X-Rays: A theoretical study of the phenomena of excitation in the nerve by different electric currents and of the biological reactions caused by X-Rays, both based upon a common principle. By J. Th. van der Werf, M.D., D.Sc. 8°, cloth, 203 pp., with 38 illustrations. New York: Elsevier Publishing Company, Incorporated, 1948. \$5.00.

This monograph is a highly technical presentation of its subject, written for physiologists and radiologists. Although the study is biologic, the author has made an extensive use of mathematics. However, two of the highly technical parts are concluded with chapters entitled "Summary" and "Conclusions," in which all the mathematics, except the fundamental equations, have been left out. The text is divided into three parts: the first consists of a general introduction and essentials (including a hypothetical equation of metabolism). In this part the author points out that the phenomena of excitation caused by electric currents, especially those of excitation of the nerve, and the biologic reactions caused by x-rays are analogous to such an extent that it is highly probable that they may be explained from a common principle. Likewise in this part, the author has tried to formulate this principle but has had to resort to higher mathematics without which the formulation could not have been made. The second part discusses the electric excitation of the nerve and the third, biologic relations caused by x and gamma rays. The pertinent literature is referred to throughout the text and instead of a regular bibliography, there is a list of the authors mentioned and the sources of their articles. There are also author and subject indexes. The book is well published in every way. The comparatively high price for such a small volume is justified by the great number of intricate mathematical formulas. The volume should be in all collections on radiology and physiology.

Diseases of the Ear, Nose, and Throat. By Douglas G. Carruthers, M.B., Ch.M. (Sydney), consulting ear, nose and throat surgeon, Canterbury District Memorial Hospital, Sydney. Second edition. 8°, cloth, 344 pp., with 140 illustrations. Baltimore: Williams and Wilkins Company, 1948. \$7.00.

The first edition of this small textbook for students and general practitioners was published in Sydney in 1943. This second edition has been revised and the use of penicillin and the sulfonamides has been included as well as the newest form of treatment for tropical otitis externa. The technique for tonsillectomy is given in detail. There is a "pharmaceutical" index, comprising standard recipes, and also an index of subjects. The text was printed in Great Britain and is well done. The publication on the whole is excellent.

Reprints from the Oxford-Loose-Leaf Medicine. By Walter C. Alvarez and others. 8°, paper. New York: Oxford University Press, Incorporated, 1948. Not for sale.

This collection of reprints comprises twenty-one articles taken from the latest edition of the *Oxford System of Medicine*. They cover the whole field of medicine and are supplied only to subscribers to the complete work and are not for sale. They are valuable to libraries because they offer in a single form various worthwhile articles that may be lent, and the bound volumes of the system may thus be kept available for reference.

Veterans Administration Technical Bulletin, Vol. 1, 1946 and 1947. 4° cloth, 240 pp. Washington, 1948. Vol. 11, 1948. 4°, cloth, 168 pp. Washington, 1949.

These two volumes for 1946-1948 contain thirty-six articles of a clinical character covering the whole field of practical medicine. They are intended primarily for the staff of the Veterans Administration. They are produced in an excellent manner by offset printing and are substantially and well bound. They should be in all reference medical libraries.

Surgery of the Hand. By Sterling Bunnell, M.D., consultant in hand surgery to the Surgeon General and licentiate of American Board of General Surgery and Plastic Surgery. First edition. 4°, cloth, 930 pp., with 779 illustrations. Philadelphia: J. B. Lippincott Company, 1948. \$16.00.

This second edition of a standard special work has been revised to bring its contents up to date since the publication of the first edition in 1944. Considerable material has been added mostly to the chapters on reconstruction, injuries, infection and tumors. Lists of references are appended to the various chapters. The book is profusely and well illustrated. There is a good index. The volume is recommended for all medical libraries and it should prove valuable to surgeons interested in the hand.

Cardiology. By William Evans, M.D., D.Sc., F.R.C.P., physician to the cardiac department of the London Hospital, physician to outpatients of the National Heart Hospital and consulting cardiologist to the Royal Navy. 8°, cloth, 330 pp., with 269 illustrations and 15 tables. New York: Paul B. Hoeber, Incorporated, 1948. \$7.50.

This condensed treatise is intended for the medical student who desires a concise book to prepare him for his final examinations. The work is based on a series of lectures given to postgraduate students at the London Hospital. The material is well organized. The text was printed in Great Britain with a good type. There is considerable waste of paper in the make-up of the index. It is surprising how many British books are being imported in pages into the United States and then bound and distributed by various publishers in preference to promotion of works by native authors. Of course, this practice is helping Great Britain in its export program.

Cancer of the Esophagus and Gastric Cardia. Edited by George T. Pack, M.D., clinical professor of surgery, New York Medical College and attending surgeon, Memorial Hospital for Cancer and Allied Diseases. 8°, cloth, 192 pp., with illustrations. St. Louis: C. V. Mosby Company, 1949. \$5.00.

This monograph is a reprint of a symposium originally published in *Surgery* for June 1948. Eighteen specialists presented eleven articles, three of which discuss the transthoracic and transdiaphragmatic methods. The publishing is excellent. The book should prove valuable to surgeons interested in the subject, and libraries could well substitute it for the bound volume of the periodical.

Shock And allied forms of failure of the circulation. By H. A. Davis, M.D., C.M., associate professor of surgery and director, Division of Surgery, Graduate School of Medicine, College of Medical Evangelists, Los Angeles Division, senior attending surgeon, Los Angeles County General Hospital and White Memorial Hospital, and visiting surgeon, Cedars of Lebanon Hospital and California Hospital. 8° cloth, 395 pp., with 55 illustrations. New York: Grune and Stratton, 1949. \$12.00.

This comprehensive monograph considers shock in all its varying aspects. Beginning with a historical introduction, including classification, the text proceeds from physiology,

biochemistry, diagnosis and pathology, through the various types of shock, and ends with treatment. The large literature on the subject is reviewed throughout the text. Long bibliographies are appended to the various chapters. There is a good index. The type, printing and illustrations are excellent. The volume is very heavy for its size, owing to the use of a hard filled paper, probably justified by the number of reproductions of microscopical slides. The book is recommended for all medical libraries and should prove valuable to surgeons and other persons interested in shock.

The Basis of Chemotherapy By Thomas S. Work, Ph.D., research staff, National Institute for Medical Research, London, and Elizabeth Work, Ph.D., research staff, Department of Chemical Pathology, University College Hospital Medical School, London. 8°, cloth, 435 pp., with 42 illustrations and 38 tables. New York: Interscience Publishers, Incorporated, 1948. \$6.50.

Here is another British book, imported in sheets and bound and distributed in the United States, but it is a good book and merits serious consideration. The authors have attempted to weld many diverse sciences into a single pattern in order to find a basis for chemotherapy. They have used the resources of organic and physical chemistry, biochemistry, bacteriology, pharmacology and therapeutics, and have analyzed and reviewed the pertinent and current literature in all these fields. The bibliography appended to the text comprises fifty-four pages. After a historical introduction, the chapters deal with cell metabolism, essential metabolites, enzyme inhibition, drug antagonism and resistance, and the relation of structure and activity of drugs. There is a good index, and the book is well printed. It should be in all reference collections in medical and scientific libraries.

The Business Side of Medical Practice By Theodore Wiprud, executive director and secretary, Medical Society of The District of Columbia, and managing editor, *Medical Annals of the District of Columbia*. Second edition. 12°, cloth, 232 pp., with 23 illustrations. Philadelphia: W. B. Saunders Company, 1949. \$3.50.

The first edition of this manual was published in 1937. This edition has been revised in part, and some of the text has been entirely rewritten and other portions expanded. New chapters on opportunities for medical leadership, group medical practice and the future of the doctor have been included in the second edition. A competent lawyer reviewed the material on the legal aspects of medical practice. There is a good index, and the book is well published. This important volume should be in all medical libraries and in the offices of all physicians.

Ghosts of the Air-Waves By Antonio L. Tauro. 12°, cloth, 165 pp. Boston: Meador Publishing Company, 1949. \$2.00.

This novel deals with the problem of unlawful abortion.

Mayo Clinic Diet Manual By the Committee on Dietetics of the Mayo Clinic. 8°, paper, 329 pp. Philadelphia: W. B. Saunders Company, 1949. \$4.00.

This manual outlines the general and special dietary procedures used in the Mayo Clinic and Mayo Foundation and the hospitals of Rochester, Minnesota, represented on the Mayo Clinic committee. In addition to the various diets an appendix contains a number of tables on foods and their special contents and on their composition, standard diabetic diets for children and for adults and height-weight-age tables for men and women. Originally, the material was mimeographed, but in this third edition it has been printed and made available to dietitians outside Rochester. A detailed table of contents takes the place of an index.

NOTICES

ANNOUNCEMENTS

Dr. Jacob B. Burke announces the opening of an office at 162 Shurtleff Street, Chelsea, for the practice of obstetrics and gynecology.

Dr. Max G. Carter announces the opening of an office at 442 Temple Street, New Haven, Connecticut, for the practice of thoracic and cardiovascular surgery.

MASSACHUSETTS CHAPTER OF AMERICAN ACADEMY OF GENERAL PRACTICE

The fall clinical meeting of the Massachusetts Chapter of the American Academy of General Practice will be held in Boston on Wednesday, October 19. The morning will be spent at clinics at the Massachusetts General Hospital, with a luncheon, afternoon papers and banquet at the Hotel Punta.

More complete details will be furnished later.

MASSACHUSETTS PSYCHIATRIC SOCIETY

The annual meeting of the Massachusetts Psychiatric Society will be held at the Hotel Sheraton, Boston, on Friday, October 28, at 7:00 p.m. The speaker will be Carl A. L. Binger, M.D., of New York City, assistant professor of clinical psychiatry at Cornell University Medical College, and formerly United States representative to the International Congress at London in 1948.

This is a dinner meeting, and reservations will be accepted from members of the medical and allied professions.

NEW ENGLAND PEDIATRIC SOCIETY

A meeting of the New England Pediatric Society will be held in Boston on Wednesday, September 28.

PROGRAM

- 11:00 a.m. - 1:00 p.m. Presentation of cases illustrating research in therapy of disseminated cancer. Dr. Sidney Farber and staff. Amphitheater, Peter Bent Brigham Hospital.
- 2:30 - 4:30 p.m. Clinical sessions conducted by Dr. Allan M. Butler and associates. Amphitheater of Building C, Harvard Medical School.
- 5:30 p.m. Refreshments. Longwood Towers.
- 6:30 p.m. Dinner. Longwood Towers (charge, \$3.25).
- 7:30 p.m. Advances in the Therapy of Infectious Diseases with the Newer Antibiotics. Dr. Emanuel B. Schoenbach, associate professor of preventive medicine and assistant professor of medicine, Johns Hopkins University School of Medicine, and physician, Johns Hopkins Hospital.

TUBERCULOSIS REHABILITATION SOCIETY

The fall meeting of the Tuberculosis Rehabilitation Society will be held at the Cedarcrest Sanatorium, Newington, Connecticut, on Friday, October 14.

The Society was organized in the spring of 1949 with a membership covering the entire New England area. Its object is the promotion of tuberculosis rehabilitation, with special reference to the exchange of technical information, the promotion of interagency and interstate relations, the development of standards for procedures and personnel in this work and promotion of publicity of tuberculosis rehabilitation.

UROLOGY AWARD

The American Urological Association offers an annual award of \$1000 (first prize of \$500, second prize \$300 and third prize \$200) for essays on the result of some clinical or laboratory research in urology. Competition is limited to urologists who have been in such specific practice for not more than five years and to residents in urology in recognized hospitals. The first-prize essay will appear on the program of the forthcoming meeting of the American Urological Association, to be held at the Hotel Statler, Washington, D. C., May 29 to June 1, 1950.

Full particulars may be obtained from the secretary, Dr. Charles H. de T. Shivers, Boardwalk National Arcade Building, Atlantic City, New Jersey. Essays must be in his hands before February 20, 1950.

HOME ACCIDENTS IN MASSACHUSETTS*

A Study in the Epidemiology of Trauma

HELEN L. ROBERTS, M.D.,† AND JOHN E. GORDON, M.D.‡

BOSTON

SELECTED features of a comparative study of accident mortality in Massachusetts and in the United States are presented here to illustrate a serious community health problem that receives too little attention. The direct objective is to determine by epidemiologic analysis the features of accident prevention that warrant special consideration in Massachusetts. We are keenly aware that to

population in 1918 to 69.7 in 1947,¹ the relative importance of accidents as a cause of death has increased, owing to improved control of other diseases. Deaths from accidents ranked fourth in 1946 in both Massachusetts and in the United States (Fig. 1), as compared with sixth position in 1935.¹

Massachusetts has a considerably lower rate than the country as a whole. The provisional rates by

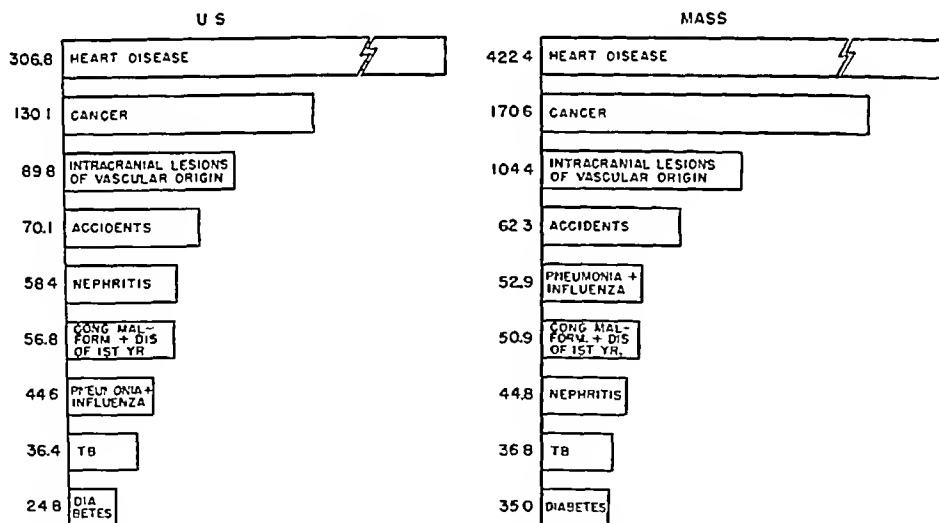

FIGURE 1 Chief Causes of Death, United States² and Massachusetts,³ 1946 (Rates per 100,000 Population)

study accidental deaths without concurrent attention to temporary and permanent disability is to under-rate greatly the medical, economic and social seriousness of the problem. In the absence of specific morbidity data, deaths necessarily serve as the index.

Although the total death rate from accidents in the United States decreased from 85.5 per 100,000

states for 1947, published by the National Safety Council,¹ give Massachusetts an enviable comparative standing, since only Connecticut, Rhode Island and New Jersey had better records. The favorable rates of recent years are no isolated circumstance. Figure 2 shows that since 1913, the death rate from accidents has been lower for Massachusetts than for the United States generally in every year except 1942, when Massachusetts suffered the Cocoanut Grove disaster. The data suggest that, in comparison with other regions, effective control measures

*From the Harvard School of Public Health departments of Public Health Practice and Epidemiology.

†Associate in public-health practice.

‡Professor of preventive medicine and epidemiology.

are already in operation or, alternatively, that citizens of the Commonwealth are, by reason of training, age or environment, more accident resistant than the residents of most other states. Unfortu-

with rates varying between 48.0 and 53.9 per 100,000 population.⁴

If accidents are divided into classes by place of occurrence (Fig. 4) the fatal accidents that occur in

FIGURE 2 Death Rate from All Accidents, Massachusetts² and United States,¹ 1913-1947

nately, the situation is not so satisfying when the rates for Massachusetts are examined more precisely.

Since 1923 the Commonwealth has had a significantly lower motor-vehicle accident death rate than the United States as a whole.³ Total accidental deaths, other than motor vehicle (Fig. 3), demon-

homes are proportionately more important in Massachusetts than in the United States generally. By contrast, motor-vehicle accidents were much less important in Massachusetts (20.2 per cent) in 1947 than in the United States as a whole (32.3 per cent). Pedestrian deaths were relatively more im-

strate no significant difference between Massachusetts and the United States over the past twenty years. When states are grouped by accidental deaths other than those involving motor vehicles, Massachusetts is in the third quartile—a group

important, as would be expected in a highly urban community. Accidents in public places (nonmotor vehicle), accounted for a larger percentage of accidental deaths in Massachusetts than in the United States as a whole. Massachusetts had a better than

average record for accidental deaths in the course of occupation

Many environmental and social conditions determine the kind of accidents peculiar to a community. In 1945 only one state exceeded Massachusetts in death rates from falls and crushing injuries.⁸ Serious falls are a function of age, and Massachusetts has an older population. This accounts in part for the observation that falls in 1946 were responsible for 26 per cent of all accidental deaths in the United States, whereas in Massachusetts the figure was 44 per cent.

reason for satisfaction. There is the added consideration that the average experience of as large a geographic area as a state cannot reasonably be used by a community to judge its individual accident problem. Variations in housing, crowding, age distribution and economic levels strongly influence the frequency and kind of accidents.

EPIDEMIOLOGY

Deaths from accidents in the United States in 1947 numbered approximately 100,000. Home acci-

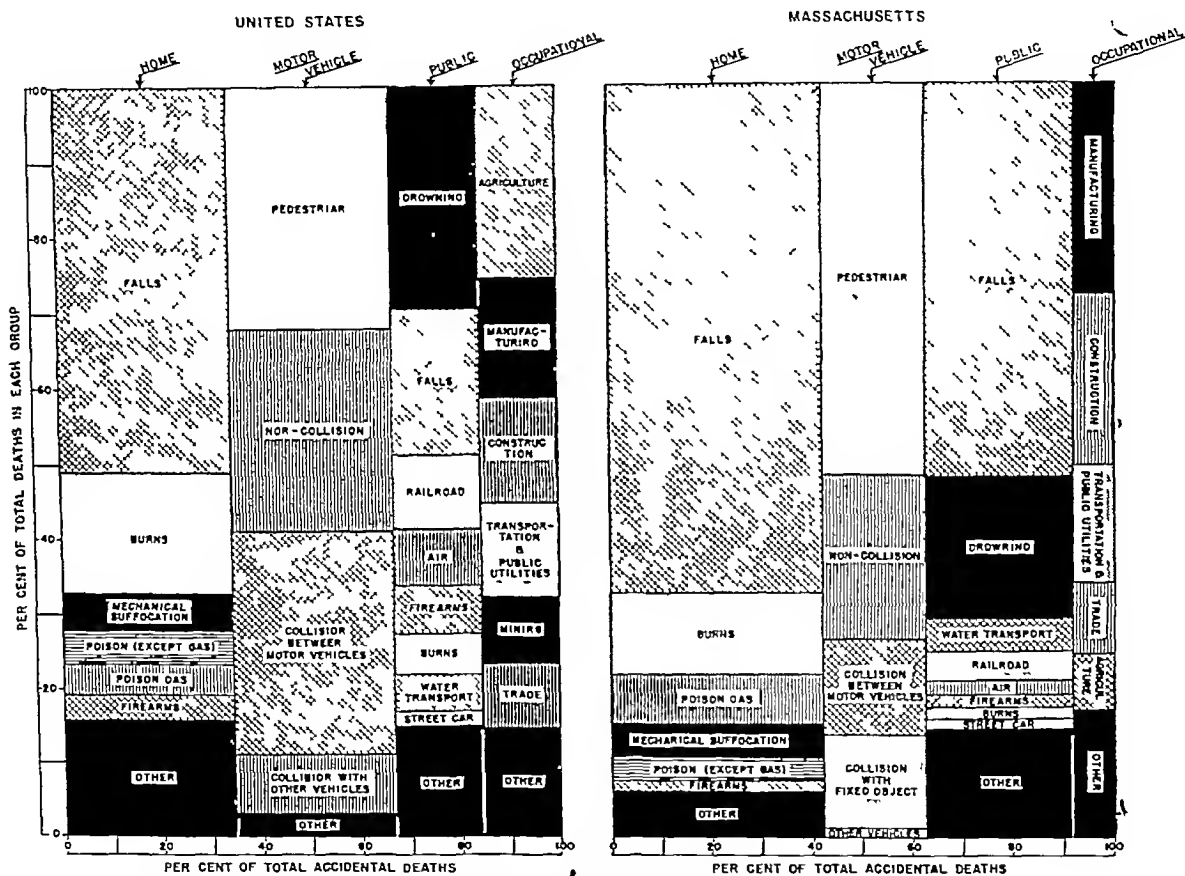

FIGURE 4 Accident Mortality, 1947, by Class and Cause, United States¹ and Massachusetts²
Based on data of Kansas State Board of Health³

Comparison of other epidemiologic variations in accidental deaths, such as seasonal and sex incidence, shows no marked differences between the two regions. The outstanding disparity that calls for special effort in Massachusetts is the excess of home and public accidents (Fig 5), falls being the paramount factor in each. That Massachusetts has a more serious problem, in these respects, is no reason for lack of attention to other areas of accident prevention. No part of the United States has so controlled accident morbidity or mortality in any age group or in any class of accidents as to have great

accidents accounted for more than a third (34,500) of the deaths and half (5,200,000) of the disabling injuries.¹ For every death from a home accident there are approximately 150 disabling injuries, of which 4 result in some permanent defect. No one of the other three classes of accidents — motor-vehicle, public and industrial — is responsible for so many deaths or disabling injuries. Home accidents alone were the ninth leading cause of death in the United States in 1946.²

The trend of home accidents, as judged by deaths, has shown remarkably little fluctuation from 1930

are already in operation or, alternatively, that citizens of the Commonwealth are, by reason of training, age or environment, more accident resistant than the residents of most other states. Unfortun-

with rates varying between 48.0 and 53.9 per 100,000 population.⁴

Much is known about age as a determining host factor. Deaths are most frequent among infants and the aged, not only because they spend most of their time in the home but also because they are least able to guard against an unfavorable environment. In 1946, 70 per cent of all fatal accidents in children under five were home accidents. Rates for infants were three or four times those for older pre-school children. Essentially two thirds of all fatal accidents that affected persons over sixty-five years of age in 1947 were home accidents, the rates being 185.0 as contrasted to 42.4 for children under five.¹ As suggested by Britten et al.,¹⁴ it may be misleading to judge the actual incidence of home accidents on the basis of death or serious disability, because an accident with serious consequences in an aged person may be of little moment for a young adult.

The kinds of fatal accident in the home differ markedly for various age groups. Burns were the most common fatal accident, in the data for the United States, at all ages under forty-five years, with the exception of persons in the age group of fifteen to twenty-four years, in which death from firearms ranked first and burns second. Falls were relatively unimportant among children, but became increasingly prominent after the age of twenty-five years, so that in persons over sixty-five years, 77 per cent of all home-accident deaths in the United States in 1946 were of this nature.¹ The Kansas Accidental Death Report⁹ points succinctly to the fact that falls in the elderly and infirm unduly weight the results. In 1947, in Kansas, 60 per cent of accidental deaths in the home were due to falls, but of these only 5 per cent involved persons under sixty-five years of age and in apparent good health.

Sex, like age, is a significant host factor. Deaths from all accidents, other than motor vehicle, involve males much more frequently throughout life than females. If only disabling home accidents are considered, as in the National Health Survey,¹⁴ males predominate up to the age of twenty-five years, and thereafter, serious home accidents happen more often to females, so that the annual frequency rate for females for all home accidents was almost one and a half times that for males. There are 2 fatal home accidents in elderly females for every 1 among elderly males.

An outstanding sex factor was noted by Brown and his associates¹⁵ in Kansas and Nassau County, Long Island: the number of boys dying in home accidents between the ages of one and fifteen years was twice that for girls, despite the reasonable belief that the hours of exposure were much the same, and certainly no greater for boys.

Environmental Factors

The causal factors arising from the environment have been studied more exhaustively than those of the agent or host. The frequency of fatal home accidents varies markedly from one state to another.

For 27 states reporting in 1947, Missouri had the highest rate, 34.5, and Utah the lowest, 16.8. Evidently the variables in home-accident rates do not correlate with total accident death rates, which were 74.5 for Missouri and a high of 82.9 for Utah. Rates vary more markedly with the concentration and type of population in a given community than with its geographic location. Thus, in 1947, home-accident death rates for urban areas were 31 per 100,000 population, for farm homes 26, but for rural nonfarm regions only 14 per 100,000.¹

Several studies have established various areas within the home as an environmental factor. An analysis of 987 fatal home accidents in Kansas and Nassau County, Long Island,¹ showed that a fourth occurred in the bedroom, because most deaths of infants and the aged were there. The yard and then the kitchen were next, followed by stairs, with other locations much less frequently the site of a fatal home accident. The studies of the Metropolitan Life Insurance Company¹⁶ of nonfatal home accidents showed the kitchen to be the most hazardous home area.

In Massachusetts³ there is a marked seasonal fluctuation in the frequency of home-accident deaths, with recurring peaks in December or January, and low rates in September, as indicated by the years 1945-47. Individual types of home-accident deaths vary markedly with season. Falls, burns of all types and deaths by poisonous gas are more frequent in the winter months, whereas deaths from poisons other than gas and from firearms show little seasonal variation. The influence of various hours of the day or night, holidays, week ends and periods of bad weather is unknown.

A marked correlation between socioeconomic factors and the frequency of home accidents is often assumed, but with little factual data to support the hypothesis. The best information comes from the National Health Survey of 1935-36¹⁴ in which the frequency rate for all home accidents causing disability of at least one week decreased from 6.01 per 1000 persons for families on relief to 4.10 for families with annual incomes of \$1000 to \$1500, and thereafter in the higher income groups a relatively stable rate was attained.

As is true of disease, no one of the three causative factors acts singly to result in the injury or produce the accident. Some one element may predominate, but ordinarily all interact. Since home accidents as a community health problem are primarily the concern of the medical profession and public-health departments, they are approached most readily and most practically by the methods that preventive medicine and public health have utilized for other health problems that affect masses of people — the epidemiologic approach. As applied to home accidents, the epidemiologic method is simply the collection and analysis of all the facts in a given area. The things to be known in terms of mortality and

to 1947. The annual rate, which is usually about 24 per 100,000 population, in seventeen years has not been less than 23, and rarely exceeds 25. An all-time high of 29 occurred in 1936. In 1947 home-accident deaths increased 5 per cent over 1946, and except for 1936, the rate was the highest on record.¹ In this uniform trend, home accidents have not paralleled the improvement shown for accidents as a whole, for industrial accidents, or for motor-vehicle deaths.¹

Six types of accidents are responsible for 85 per cent of home-accident deaths. Falls are numerically

Earlier publications^{7, 8} have shown that accidents follow the same biologic laws as other morbid processes that involve groups of people, and hence are susceptible to the same methods of epidemiologic study so valuable in the communicable diseases and now applied to mass disease in general — to diabetes, cancer and many others.

The collection and arrangement of home-accident data according to etiologic factors that relate to agent, host and environment are believed essential to proper weighting and evaluation. They permit specific preventive measures to be applied to important causes in a given community. This framework is now used to present some of the known epidemiologic facts about home accidents and to gauge the need for the collection of added information.

Etiologic Agents

The usual classification of home accidents by type is useful in describing the mechanism of injury, but does not provide information about the direct causative agent or the activity of the victim at the time of the accident. If the accident is a burn, was it due to smoking in bed, to a child playing with matches in the mother's absence or to defective electrical wiring? The potential number of agents in falls is even greater than that for burns, and to classify all such accidents by mechanism alone is to mask the causative relation of such dissimilar agents as a misplaced toy, structural defects in a building and a hole in a driveway.

A few investigators^{9, 11} have studied specific agents in home accidents, but the knowledge thus gained is far from adequate. No studies have included the home accidents that disable the person for only a day or so. No one has enough data to evaluate the varying importance of a particular agent in different geographic areas or under diverse conditions of living, as in rural and urban regions.

Host Factors

Except for the simpler matters of age and sex, host factors have been largely ignored in home-accident studies, although receiving much attention in motor and industrial accidents. They are increasingly appreciated as significant etiologic factors in all accidents. The analyses published by the Kansas State Board of Health⁹ suggest the importance of existing physical disability, especially in the older age groups. The relation of temporary emotional tensions to home accidents is unknown, as is the role of alcohol and drugs. It is known that some people have an unusual number of accidents in any situation, and that this proneness is unrelated to intelligence, reaction time, experience or physical constitution. Accident proneness has been studied in motor¹² and industrial accidents,¹³ but its part in home accidents has yet to be appraised.

FIGURE 5 Comparison of Accidental Death Rates by Class of Accident, United States¹ and Massachusetts,⁵ 1945-47

the most important, accounting for 17,600 deaths in the United States in 1947, or more than half of all fatal home accidents. This was more than three times the number in the next most frequent category, which was burns, scalds and explosions. Since mechanical suffocation affects infants almost exclusively, it is surprising that it ranks third, with poisons other than gas, poisonous gas and firearms next in order of frequency.¹

Home accidents as a problem of community health have had minor attention in an analysis of cause, when cause is interpreted epidemiologically according to three principal factors. These are the direct etiologic agent, such as the micro-organism in a communicable disease or the loose floor board in a home accident, the characteristics of the host who develops the disease or suffers the accident, and the environment in which the host and the agent exist.⁷

Much is known about age as a determining host factor. Deaths are most frequent among infants and the aged, not only because they spend most of their time in the home but also because they are least able to guard against an unfavorable environment. In 1946, 70 per cent of all fatal accidents in children under five were home accidents. Rates for infants were three or four times those for older pre-school children. Essentially two thirds of all fatal accidents that affected persons over sixty-five years of age in 1947 were home accidents, the rates being 185.0 as contrasted to 42.4 for children under five.¹ As suggested by Britten et al.,¹⁴ it may be misleading to judge the actual incidence of home accidents on the basis of death or serious disability, because an accident with serious consequences in an aged person may be of little moment for a young adult.

The kinds of fatal accident in the home differ markedly for various age groups. Burns were the most common fatal accident, in the data for the United States, at all ages under forty-five years, with the exception of persons in the age group of fifteen to twenty-four years, in which death from firearms ranked first and burns second. Falls were relatively unimportant among children, but became increasingly prominent after the age of twenty-five years, so that in persons over sixty-five years, 77 per cent of all home-accident deaths in the United States in 1946 were of this nature.¹ The Kansas Accidental Death Report⁹ points succinctly to the fact that falls in the elderly and infirm unduly weight the results. In 1947, in Kansas, 60 per cent of accidental deaths in the home were due to falls, but of these only 5 per cent involved persons under sixty-five years of age and in apparent good health.

Sex, like age, is a significant host factor. Deaths from all accidents, other than motor vehicle, involve males much more frequently throughout life than females. If only disabling home accidents are considered, as in the National Health Survey,¹⁴ males predominate up to the age of twenty-five years, and thereafter, serious home accidents happen more often to females, so that the annual frequency rate for females for all home accidents was almost one and a half times that for males. There are 2 fatal home accidents in elderly females for every 1 among elderly males.

An outstanding sex factor was noted by Brown and his associates¹⁵ in Kansas and Nassau County, Long Island: the number of boys dying in home accidents between the ages of one and fifteen years was twice that for girls, despite the reasonable belief that the hours of exposure were much the same, and certainly no greater for boys.

Environmental Factors

The causal factors arising from the environment have been studied more exhaustively than those of the agent or host. The frequency of fatal home accidents varies markedly from one state to another.

For 27 states reporting in 1947, Missouri had the highest rate, 34.5, and Utah the lowest, 16.8. Evidently the variables in home-accident rates do not correlate with total accident death rates, which were 74.5 for Missouri and a high of 82.9 for Utah. Rates vary more markedly with the concentration and type of population in a given community than with its geographic location. Thus, in 1947, home-accident death rates for urban areas were 31 per 100,000 population, for farm homes 26, but for rural nonfarm regions only 14 per 100,000.¹

Several studies have established various areas within the home as an environmental factor. An analysis of 987 fatal home accidents in Kansas and Nassau County, Long Island,¹ showed that a fourth occurred in the bedroom, because most deaths of infants and the aged were there. The yard and then the kitchen were next, followed by stairs, with other locations much less frequently the site of a fatal home accident. The studies of the Metropolitan Life Insurance Company¹⁶ of nonfatal home accidents showed the kitchen to be the most hazardous home area.

In Massachusetts² there is a marked seasonal fluctuation in the frequency of home-accident deaths, with recurring peaks in December or January, and low rates in September, as indicated by the years 1945-47. Individual types of home-accident deaths vary markedly with season. Falls, burns of all types and deaths by poisonous gas are more frequent in the winter months, whereas deaths from poisons other than gas and from firearms show little seasonal variation. The influence of various hours of the day or night, holidays, week ends and periods of bad weather is unknown.

A marked correlation between socioeconomic factors and the frequency of home accidents is often assumed, but with little factual data to support the hypothesis. The best information comes from the National Health Survey of 1935-36¹⁴ in which the frequency rate for all home accidents causing disability of at least one week decreased from 6.01 per 1000 persons for families on relief to 4.10 for families with annual incomes of \$1000 to \$1500, and thereafter in the higher income groups a relatively stable rate was attained.

As is true of disease, no one of the three causative factors acts singly to result in the injury or produce the accident. Some one element may predominate, but ordinarily all interact. Since home accidents as a community health problem are primarily the concern of the medical profession and public-health departments, they are approached most readily and most practically by the methods that preventive medicine and public health have utilized for other health problems that affect masses of people — the epidemiologic approach. As applied to home accidents, the epidemiologic method is simply the collection and analysis of all the facts in a given area. The things to be known in terms of mortality and

morbidity are when and where accidents occur, how they occur and to whom the accident happens. This includes a study of the site of the accident, the behavior and characteristics of the person affected, his activities at the time of the accident and, finally, the specific agent causing the accident.

Blanket-control measures have proved unproductive and expensive in any public-health program. What is needed is sufficient knowledge of the occurrence of the disease in a given community to permit a specific attack on the principal problems presented and on the most accessible link in the chain of causation. To date, not only is knowledge of the circumstances of home accidents for the country as a whole insufficient but also the available data are too often collected indiscriminately and tabulated without definite epidemiologic objectives. An evaluation of the home-accident problem, based on deaths alone, results in a distorted view of the situation.

Since home accidents vary markedly from community to community, and since few regions have adequate knowledge of nonfatal home accidents, or of the circumstances surrounding fatal mishaps, we believe that a town or county can, to advantage, study its own home accidents as the first requisite to an efficient control program. Similarly, a state control program should be preceded by representative studies of the population with samples drawn from rural, industrial, suburban, village and town areas. The kind of accident study will depend on the method selected for finding cases, and upon the finances and personnel available. The survey may be one or a combination of the following:

Study of accidental deaths in the community. An analysis of deaths resulting from accidents, without subsequent study of accidents of less serious consequence, omits the bulk of accidents in the community. As a preliminary, such a study may be valuable, particularly if a complete, individual analysis of the circumstances of each death is made. Such studies of fatal accidents in Kansas over prolonged periods have added materially to knowledge of accident etiology.

Study of home-accident cases admitted to hospitals. Most of the more serious home accidents may be assessed by a continuing study of admissions to hospitals within the area. Hospital records alone are usually insufficient to supply the necessary epidemiologic data, but can be enlarged by an accident history obtained from the patient or a member of his family, a study of the site of the accident and the co-operation of the attending physician.

Organized survey in selected areas. The most satisfactory epidemiologic data are obtained by household-to-house survey, using trained investigators and a sufficiently large sample of the population to ensure statistical accuracy. It appears purposeless to study accidents with a disability of less than one day, if the index is a disability as long as a week, many

socially and economically important accidents will be missed, especially among children and young adults. Therefore, a disability extending beyond the day the accident occurred is a reasonable inclusion index. The obvious disadvantage of the organized survey is cost, which for many communities is prohibitive.

Incorporation of the accident study into the routine activities of the health department. This is a reasonable compromise. If the health department is making other continuing surveys, the accident study may be included, using the same personnel entering the home for the original study. What is even more practical, the public-health nurse may inquire about the circumstances of home accidents as a part of visits for other purposes. Such studies are now under way in two suburban towns in Massachusetts, and a third has been started by the health department of a large industrial community. In each region, the nurses of voluntary agencies and of the health department co-operate in investigating and recording accidents occurring on home premises within the preceding thirty days.

A convenient record form provides the necessary epidemiologic data for developing a specific educational program. The household roster, often already in the nurses' record, is used as a base in the calculation of hours of exposure. Persons other than nurses may aid in such studies, but we have no experience as yet to indicate how necessary trained personnel and professional qualifications may be in the success of the survey.

The ultimate control program, as described by Brightman¹⁷ for New York State and by the Subcommittee on Accident Prevention of the American Public Health Association,¹⁸ will center around education, especially directed to groups of people who have the most accidents. It will include continuing epidemiologic studies, case finding and the treatment of the accident prone, especially children. Administratively, experience must be accumulated on what constitutes a feasible control program, and on the means for evaluating the success of a program.

SUMMARY

The interest in accidents engendered by the modern motor car and long fostered by industry has, in recent years, been extended to the other and numerically more important accidents that occur in the home. There is need for greater appreciation of the costs of accidents and realization of the fact that they can be prevented. The obligation of the moment is to co-ordinate the activities of multiple voluntary and official community agencies into an effective home-accident control program. Its success depends on the same analytic and scientific methods by which all community health problems are approached: the epidemiologic survey.

THE NEEDS FOR INPATIENT CARE AND TREATMENT OF MENTALLY ILL CHILDREN IN THE COMMONWEALTH OF MASSACHUSETTS

THADDEUS P. KRUSH, M.D.*

WALTHAM, MASSACHUSETTS

IN PSYCHIATRY in the past thirty years there has been a gradual increasing interest in progressing downward along the chronologic scale toward childhood to seek out the earlier phases of personality deviations. To search for a means of straightening the bent twig while it is still in the process of bending appears all too obvious, but the surprising feature is the fact that it has taken so long to turn attention in this general direction. That the "hopeful" aspect of psychiatry exists in child psychiatry should be reasonably apparent to anyone who has spent long hours in individual or group therapy with mentally ill adults in an attempt to delve backward into their repressed conflicts or to enable them to obtain sufficient insight to be able to accept and deal with their environmental stresses of the moment. These patients have been chronically ill by the time that clear-cut psychotic or psychoneurotic adaptations appear.

Except in extreme deviations, the child exhibits no such well defined clinical syndromes, but the need for closer observation and classification is here necessary if the developing dynamisms of adult mental illness are to be better appreciated.

Although child guidance has done much to add to knowledge in this respect, there also appears to be a need for inpatient care and treatment of mentally ill children, particularly those exhibiting problems centered around marked withdrawal, running away, extreme aggressiveness and hyperactive-distractable types of behavior. The first named need hospitalization to be afforded a permissive, noncompetitive haven, the second need

to be maintained in a therapeutic situation for a sufficient length of time to form a relation with the therapist and more adequately to test reality, the third need some environment to contain aggressiveness until they become more aware of the source of their hostility, for they certainly do not become more secure nor is their antagonism abated by a continual shuffling of foster homes, the fourth need investigation of the central nervous system for diffuse neurologic defects and a mobilization of intellectual assets in a nonfrustrating environment. All need a multidiscipline approach to their personality disabilities to assure as rapid rehabilitation to society as possible.

In December, 1945, the Metropolitan State Hospital was designated by the Massachusetts Department of Mental Health as the institution to which all psychotic children in the Commonwealth were to be sent. During this and the following months, such psychotic children as were scattered throughout the Department's institutions were transferred to this hospital, which then began to receive severe behavioral deviants from the community. Two 50-bed wards were taken from existing overcrowded adult facilities to house the increasing influx of children. A critical evaluation of the inpatient mental facilities for children in the state is in order so that reasonable short-term and long-term goals can be established to achieve care and treatment of this group of the population.

In Massachusetts approximately 23,000 adults are at present patients in state mental hospitals. If the seed of mental illness is planted during childhood, to come to full fruition in adulthood, it seems likely that more than half of 1 per cent of the

*Clinical director of psychiatry, Children's Unit, Metropolitan State Hospital.

present capacity of institutions should be set aside for the study, care and treatment of children's mental disorders. The present admission rate of approximately 300 per year tends to confirm the need for this type of hospitalization.

Some alteration of the scope and purpose of this unit, originally conceived as one to which psychotic children could be sent for care and treatment, has been necessary, owing to the following circumstances: the prevailing types of commitment procedures, the existing confusion regarding what constitutes psychosis in childhood and the community needs for the mentally ill child.

At present a patient may be committed to the Children's Unit under Section 79, 77, 51, 100, 86 or 86A of Chapter 123 of the *General Laws*. With the exception of Sections 86 and 86A no refusal of admission exists, hence, practically all children sent to the unit are admitted, physical facilities notwithstanding. Although this is moderately frustrating to the personnel involved in the diagnosis, care and treatment of these children such procedures serve the useful purpose of funneling all patients under the age of sixteen considered by the Commonwealth to be mentally ill.

Even the most cursory examination of the field of child psychiatry reveals the fact that the diagnosis "psychosis" as applied to a childhood behavioral deviation is an ill defined entity, subject largely to the individual or staff interpretation of the moment. Considerable complication arises because of the wide range of "normal" necessitated by the uneven rates of physical, intellectual and emotional progress in the child. Here, too, one would expect to see mental illness in its nascent state rather than in the better defined chronic states as seen in adults. It appears more reasonable to accept such behavioral deviants who have demonstrated an incapacity to adjust themselves satisfactorily in an outside environment. Children with severe behavior disorders, not classifiable as psychotic but demonstrating prolonged and continuous maladjustment, would then be eligible for more protracted treatment than that given during the thirty-day observation period. As long as the emphasis on treatment and rehabilitation to society is stressed, no child will be unjustly incarcerated for an excessive period.

The existing physical facilities, largely located in the medical and surgical building of the Metropolitan State Hospital, consist of two 53-bed wards, the overflow from the boys' ward being housed on the male admission ward, a small solarium utilized for group psychotherapy, two small rooms used as classrooms, a basement playroom, two playgrounds located between the medical and surgical wings, tennis courts, bowling alleys and a gymnasium, the last three being shared with the adult patients. A five-room suite located between the wards contains an examining room, psychologic testing room,

doctor's office and two small recreational-therapy rooms.

The most urgent physical need centers around the 50-bed wards, which, originally designed for tractable adult patients, have proved too large to be manageable with 50 patients of great destructive capabilities. Obviously, a situation close to chaos would result if one admitted to the ward the most marked behavioral deviants from the following sources: Fernald State School, New England Home for Little Wanderers, Court cases pending disposition, Monson State Hospital, Lyman School for Boys, Shirley Industrial School and severely regressed and withdrawn children from the community. Only the simplest form of segregation into three groups can be effectively maintained.

These basic groups are a "deteriorated" group, the members of which need total custodial care, feeding, bathing, toileting, clothing and so forth, a "middle" group, whose members, although able to care for their own immediate physical needs, are in need of constant supervision, training and guidance, and a "self-sufficient" group capable of meeting the demands of hospital environment — that is, of assisting in ward housekeeping, kitchen duties and so forth. Such a system is at present in effect.

Adequate segregation and classification are practically impossible under such circumstances, and treatment is seriously handicapped, since carefully fostered relations between personnel and patients must frequently be strained by administrative expediency.

It is proposed that any specially constructed children's unit be composed of small family-size wards consisting of not more than 10 beds to each ward. On the basis of the present admission rate, which is still increasing, it seems reasonable to expect that approximately fifty such wards would begin to meet the needs expressed by schools, courts and community. An initial nucleus of fifteen such wards is immediately necessary, additional wards being added in a definite building program designed to fit the unit to its average patient load over a period of five to ten years. Durability, safety, ease of maintenance and access, rather than beauty of design, are prime considerations.

The most acute need of this unit is at present for personnel. A subminimal nucleus of interested, enthusiastic and somewhat frustrated persons consists of 2 doctors, a nurse, a social worker, a psychologist, a recreational therapist, and a clerk, with positions for occupational therapist and an additional nurse remaining unfilled. No provision for a separate group of attendants especially trained for work with children exists. The 13 attendants now serving on these two wards are "borrowed" from the attendants allotted the hospital for the care of adult patients.

A more detailed study of the medical needs of such a unit reveals that the physicians occupying

the positions of clinical director and assistant physician work up approximately 400 cases each year (more than 300 inpatients in addition to outpatients, chiefly committed by the courts for appraisals). Study of each inpatient consists of a social history, physical examination, laboratory examination, including an electroencephalogram, and psychiatric examination. In addition, the care of 100 regularly committed patients is administered by these 2 men. No pediatric consultant other than the regular medical and surgical consultants of the hospital is available. No formal outpatient linkage with the community is provided, though if the accent is to be on treatment and resocialization of patients, such an association is vital. Furthermore, the patients passing through and being retained in this unit represent a potential mine of information regarding early and late behavioral deviations. Proper collection and assortment of the mass of data necessary for careful study require a larger force than the bare minimum of 1 psychiatrist to 200 patients.

A proposed minimal medical staff should consist of a director, a senior physician, a consulting pediatrician, 2 assistant physicians, 2 residents in psychiatry and 4 fellows drawn from the fields of psychiatry, pediatrics and anthropology. The need for a director of such a unit is apparent. His duties should consist of co-ordinating the therapeutic and investigational work to maintain maximal efficiency with the personnel at hand. He should be responsible for decisions regarding policy and for the concerted efforts of his staff in an effort to educate the community regarding the needs of the mentally ill child. The efforts of the senior physician should be utilized in the direction of an outpatient department designed to provide the necessary community linkage, follow-up study and continued treatment of patients well enough to function on an outpatient level. Assistant physicians should be available in the ratio of 1 to every 5 10-bed wards, or 1 for each of the present 2 wards to meet the immediate needs of their wards, to carry out individual and group psychotherapy and to work on investigational approaches designed to enhance the understanding and therapy of mentally ill children. Two residents would provide training for a psychiatrist, six months each, on male and female services. An opportunity to provide shorter term training to supplement the other training programs could be met by a fellowship rotation with pediatric-psychiatric facilities maintained by general or pediatric hospitals. Such three-month indoctrination periods would provide a larger group of physicians with a better understanding of the problems confronting the mentally ill child. Judging from the large number of obvious deviations of growth in this group there seems to be a fertile field for an anthropologist to study at this level.

Since the present two-ward system obtains, the nursing problem has been estimated on this basis

Provision has been made for 2 registered nurses to provide the nursing care for the unit. This allows for coverage of each ward by nurses for forty hours a week, or less than a quarter time coverage by such personnel.

The degeneration of ward administration and treatment during the absence of nurses on the ward is all too painfully apparent, particularly on the boys' ward, where a woman's forbearance and restraining hand are sorely needed to modify the fluctuating disciplinary extremes of male attendants. With twenty-four-hour nursing care, it would not be necessary to transfer the child to the adult medical and surgical wards for treatment of accidents and illnesses not requiring isolation. It is estimated that 8 graduate nurses could provide such coverage for the present two wards. Two supervisors would be necessary to co-ordinate the unit's nursing activities. With such a staff augmented by 6 graduate student nurses obtained from a university nursing school, in addition to 4 student nurses affiliating at this hospital, such procedures as hydrotherapy and insulin therapy could be provided. At present, 4 student nurses on affiliation to the hospital gain valuable experience in mental illness only so long as a registered nurse is on duty. Their training is augmented by a two-hour clinic each week in which an attempt at altering their attitudes from apathy or hostility to acceptance of the problems presented by the patient is made. It is realized that the numbers of nurses suggested above are not available in the present-day shortage of nursing personnel so that immediate interim nursing needs should be aimed at obtaining at least 1 supervisor, 4 registered nurses, 2 graduate students and 4 student nurses to provide minimal coverage.

An additional phase of the nursing problem has to do with the attendant personnel, at present consisting of 13 assorted persons varying from those who are sincerely interested in the welfare of the patients whom they attend to representatives of the economic, social and moral fringe of society, who are attracted only by the possibility of drawing a pay check every Thursday. The present-day labor shortage and low income obtainable in this field place the accent on the latter situation, with the result that this group is highly unstable.

This fact has been demonstrated on several occasions during the process of carrying on group therapy with the patients. Basic insecurities of the attendants are activated, necessitating some group therapy of the attendants themselves. It is unfortunate that the most unstable group is numerically the largest one utilized in patient care and the group constantly in contact with the patients. More complete nursing coverage as suggested, coupled with a practical teaching program carried out by the physicians, would go a long way toward stabilizing such a group.

Social-service coverage at present is provided by the head of the department, a staff worker and 2 students. On the basis of a recent report,¹ the present inpatient and intake load will require a supervisor and 6 staff workers, in addition to the present head of the department. Augmentation of the force dealing with the manifold social problems inherent in mental illness could be accomplished by assignment of a psychiatric-social-work student to each staff worker, the supervisor acting as case consultant for these workers. Valuable insights into patient's problems are at present provided the social-service department by utilization of members of this force in group-therapy situations. Pending the achievement of the goals mentioned above, the head worker should have at least 3 staff members supplemented by three students assigned to the Children's Unit.

In the field of psychologic testing there is available at present the position of a psychologist. It is estimated that 2 psychologists are needed to cope with the present patient traffic.^{2, 3} With the addition of 2 student psychologists the necessary "battery" testing of the patients would be accomplished in a fashion designed to accumulate and analyze data in this field as an aid in more accurate classification and treatment.

From the standpoint of education, provision at present is made for the position of a teacher—1 teacher for 125 of the most disturbed "pupils" in the Commonwealth. There is a singular educational apathy toward the teaching problem posed by the unit, even though it seems apparent that here exists "exceptional" child material that should provide a real proving ground for educational methodology. The transference of results obtained with such children should prove valuable in reorienting the educational approach toward the "fringe" children of the regular and special classroom. To cite a possible example of investigation, the relation of reading disability to early primary behavior disorders should prove a fruitful source of endeavor.

Furthermore, work in this field should be supervised by competent investigators, preferably from a university graduate school of education. It is unlikely that the psychiatrist's life span will be long enough for him to master the fields of medicine, education, sociology and penology in all their details. Hence, it is not reasonable of the Department of Education to step aside on the plea that provision for such a specialized staff should be made through the Department of Mental Health. Although physicians have been exposed to lengthy educations, this in turn does not make them educators, and it seems wiser for these two disciplines to act in concert rather than to attempt to wash their hands of the matter. The least that should be done by the Department of Education is to appoint an advisory board for such a specialized educational problem.

It is estimated that a minimal educational staff should consist of a head teacher and 4 staff members, each of whom could augment his teachings by supervising a graduate student in education for each 100 patients, roughly comprising 50 per cent of patients of normal intelligence, 25 per cent of educable mental deficient and 25 per cent of custodial mental deficient. This estimate is probably inadequate and is subject to revision as better understanding of the educational problems becomes apparent to the psychiatrist.

Aside from these academic aspects, it would be advisable to provide social and vocational training. To a slight degree in small group situations, progress in the social field is at present being made. This entails the use of social workers who eat at least one meal a week with the children. Further attempts at acquiring some proficiency in household duties is afforded in another group setting off the ward. At present, no form of vocational therapy exists owing to the lack of facilities. With the exception of the last named, no new personnel would be necessary, provided a plan for training of ward personnel, including social integration as part of their duties, was made.

Provision is made for an occupational therapist, but at present such a position remains vacant. At least 2 occupational therapists should be assigned to the unit as an initial effort. One of these should be qualified to serve as a co-ordinator of play therapy and psychodramatic technics, and the other should utilize manual-training skills in a small group setting.

At present a recreational therapist is carrying a great deal of the load of play therapy in a group setting (party projects, roller skating, tennis, bowling, sledding and so forth). For the purpose of group control some supplementation of personnel is made available through attendants and student nurses at a resultant sacrifice in efficiency of ward administration. At least 2 counselor assistants, possibly drawn from the field of group work of a school of social work, are needed, particularly from the standpoint of the juvenile delinquent who comes to the unit for a period of observation.

As a supplement to occupational and recreational therapy, community group activities designed to provide a link with society when the child is returned to the community are established, but are as yet functioning poorly. Boy Scout and Girl Scout activities of this sort are attempts at providing such a transition.

In the realm of motion pictures, the productions have been largely recreational, but more recently use has been made of educational films as well. This could be greatly supplemented by membership of the unit in a university educational film library for the purpose of obtaining visual teaching aids.

Although religious education of these children should be neither rigidly directive nor compulsory,

it should be available to the degree that would meet each child's religious need. The Catholic clergy, and to a lesser degree, a Protestant minister, are at present attempting, within the confines of their respective religions, to meet this need. It seems advisable, in view of the lack of moral concept apparent in some patients, that such education should be made available without coercion. An inter-faith advisory board composed of interested clergy could best indicate how this might be carried out in an institutional setting.

From the legal standpoint, such a unit as this becomes increasingly important, directly as the judiciary and law-enforcement agencies recognize the fact that punishment does not always fit the crime. It is not our intent to pamper persons who have clearly demonstrated antisocial tendencies, particularly if the offenses are aggressive and capable of inflicting injury on others, but the apparently prevalent view that "what they need is a good lashing" is not subscribed to, firstly because many of these patients are almost literally driven to their expression of antisocial behavior by such a social attitude so far as can at present be observed, and secondly because the motivation of antisocial behavior should be studied for the valuable insights that will be necessary for its control and prevention. Such insights will not be forthcoming by the use of coercive measures. Particularly is this true in the field of sexual deviation, in which the sensibilities of many people seem to be so sorely offended, judging by the resultant hue and cry when the public is afforded the opportunity of harrying one of these unfortunate persons into a prison.

Provision for the juvenile delinquent in this unit is predicated on the belief that he represents a sufficiently aberrant behavioral pattern to be classified as mentally ill—hence, the need for observation and treatment rather than custodial care. This is not intended as an argument for the emptying of prisons into the mental hospitals, but rather as a plea for extension of psychiatric facilities to the penologic system. A unit such as this can serve largely for classification, aiding in the more complete evaluation of the social offender and as a treatment unit for selected research problems in this field. At present well over 50 per cent of admissions are at the behest of law-enforcement agencies, and it appears that some steps in the correct direction are in the process of being taken by the Youth Service Board.

The clerical needs of the unit cannot in actual practice be met by one clerk, as is provided in the present table of organization, so that at present this position is pooled with the clerical help of the rest of the hospital to obtain an even apportionment of the work to the available clerks. In this fashion, the minimal needs are at present met, with some consequent sacrifice of the clerical efficiency of the rest of the hospital. It appears that at least 3 clerks are necessary to accomplish the present unit record work, particularly in view of the fact that a greater portion of the outpatient work is at present done in penciled notes. With some semblance of adequacy in this department, the records and clerical personnel should then be moved closer to the actual patients, the information previously obtained by the personnel being thus more readily available for the purpose of treatment and research.

The present medical administrative routine is that the superintendent and the assistant superintendent deal with the problems of housing, clothing, feeding and medical supply, attempting to meet the increasing needs of the unit through the regular hospital budget. Since the budget is planned at least a year in advance, the expanding needs of the unit can never be met even minimally. Until a more realistic attitude is taken regarding the expanding budgetary needs, the unit must continue to be society's orphan, begging for its very existence.

From the economic standpoint in the operation of a unit such as this, the experience garnered in the past three years indicates that the Commonwealth has been functioning in a manner similar to that attributed to "Peter at the Dike," stuffing his arm into the leak in the dike to prevent its being washed away completely. The continual destruction and repair necessitated by the large unmanageable wards falls into such a category.

From the standpoint of adequately serving the Commonwealth, it is necessary that a departure from the present available setup be made, preferably along the lines indicated above. It is realized that the initial expenditure would be considerably more than that at present being dribbled away in a year's time. However, over a longer period, it is apparent that a well integrated unit, designed to meet the needs expressed by the Commonwealth, would be more efficient and less costly than the present attempt at patching inadequate facilities.

A PUBLIC-HEALTH HEART PROGRAM — FIRST REPORT*

EGON E. KATTWINKEL, M.D.,† VLADO A. GETTING, M.D.,‡ ERNEST M. MORRIS, M.D.,§
HERBERT M. LOMBARD, M.D.,|| AND LEWIS C. ROBBINS, M.D.||

BOSTON

IN MAY, 1948, the Massachusetts Medical Society endorsed in principle a pilot study of the public-health aspects of heart disease.¹ The study was to be conducted in Newton under the joint sponsorship of the Newton Health Department, the Massachusetts Department of Public Health and the United States Public Health Service.² Its objectives were to determine methods of helping to reduce cardiovascular disease and conserve cardiac function.

A period of a year does not allow sufficient time to draw definite conclusions or submit findings for qualitative or quantitative analysis. However, it does seem fitting to report to the Massachusetts Medical Society concerning the activities that have been initiated and to indicate the direction of the program.

The Newton Heart Demonstration Program, as the pilot study has since become known, is a frankly experimental venture. It rests largely on a belief — held by many cardiologists and public-health authorities — that heart disease constitutes a public-health problem.³ Mortality statistics show that deaths from diseases of the heart exceed those from any other cause.⁴ Many other criteria usually considered before establishing public-health programs remain undetermined when applied to heart disease. For example, how many people in a community are actually ill of heart disease? What is the age at which they are affected? To what extent can heart disease be prevented? How much salvage can be effected for those in whom the disease in one of its forms develops? What aspects of the problem cannot be met except by community measures? And what is the cost of these measures? Finally, what evidence is there that public-health measures will yield results?

Many heart studies will probably be needed to provide answers to these questions. But the United States Public Health Service initiated a local study in an attempt to determine the value of organized community action in helping to meet cardiac needs, and the costs and effectiveness of such action.

The Massachusetts Department of Public Health was asked to co-operate. The Commissioner obtained the assistance of the Committee on Public

Health of the Massachusetts Medical Society. Also, the Commissioner appointed a technical advisory committee of leading cardiologists and public-health authorities.

It was believed desirable to conduct the study in a community that employed a full-time, trained medical health officer and furnished basic public-health services. Several communities were surveyed. Newton was selected, and a unit of public-health-service personnel, previously assigned to the Commissioner, was reassigned to the Newton Director of Public Health.

The co-operation and leadership of the Newton medical profession were considered essential. The practicing physician represents the greatest potential source of knowledge of the cardiac problem in the community. With him rests responsibility for diagnosis and treatment of the patient with heart disease. Supplementary services may contribute to the patient's welfare, but they can only be utilized under the supervision of the physician. The key place that the practicing physician naturally occupies was therefore the major consideration in the plans for the heart program.

When the demonstration had become established in the health department, the Director of Public Health and the Medical Officer of the unit requested the assistance of the Newton Medical Club. The President assigned the Committee on Public Health to work with the health department to explore program possibilities and develop preliminary plans. At the request and under the supervision of the Committee, a small survey of the cardiac patients of private physicians was made. The survey, although not statistically significant, yielded information concerning the extent to which existing facilities for cardiac patients were being used, and indicated some of the social and public-health problems of heart disease. On the basis of the findings, a tentative outline of activities for the Heart Demonstration Program was drawn up and presented to the Newton Medical Club, which, in October, 1948, gave its unanimous endorsement.

Medical guidance for the Newton Heart Demonstration Program today lies with a group of 6 physicians known as the Cardiac Program Committee. This committee was appointed by the president of the Medical Staff of the Newton-Wellesley Hospital. Members include 5 internists, 3 with special interest in heart disease, and a pathologist.

*Presented at the annual meeting of the Massachusetts Medical Society, Worcester, May 24, 1949.

†Chairman, Cardiac Program Committee, Newton Heart Demonstration Program.

‡Commissioner, Massachusetts Department of Public Health.

§Director of public health, Newton Health Department.

¶Chief, Division of Cancer and Other Chronic Diseases, Massachusetts Department of Public Health.

||Medical officer in charge, Heart Demonstration Programs, United States Public Health Service.

The functions of this committee are to furnish technical leadership and share jointly with the health department in planning the heart program. The Director of Public Health and the Medical Officer of the program meet with the committee once a month or more. The first meeting was held on December 3, 1948.

FIRST FIVE STEPS

After several months of study, a five-point program was recommended for early action. It called, first, for a well informed medical profession, since any services made available to the cardiac patient would be given either by the physician or under his supervision. Secondly, information on the amount and kinds of heart disease occurring in Newton was needed to permit more intelligent program planning. Thirdly, the participation of the public was desired to ensure full use of community resources. Fourthly, a study of the dietary needs of cardiac patients appeared necessary since nutrition touches upon many aspects of prevention and treatment. And, finally, the rehabilitation needs of the patient required investigation if he was to receive full benefit from medical treatment.

Subcommittees were established for the further study and development of the five steps. They included physician education, temporary voluntary reporting, community organization, nutrition and rehabilitation. A sixth subcommittee was set up to consider additional program possibilities.

Subcommittee on Physician Education

The goal of the subcommittee on Physician Education is to contribute to the improvement of diagnosis and treatment of heart patients in Newton. Knowledge of heart disease is advancing rapidly. Every additional development offers new hope and carries with it responsibility for improving the care of the cardiac patient. To help Newton physicians keep abreast of the developments the Cardiac Program Committee is sponsoring monthly discussions of modern cardiology known as the Newton Postgraduate Heart Institute. A serious attempt is being made to keep the discussions practical and to foster audience participation. Content is based on interests and needs of local physicians as indicated by a preliminary questionnaire and the expressed wishes of those attending the meetings. The first two sessions included talks on "Practical Aspects of Heart Disease" and "Prevention of Heart Disease." The third meeting will be a discussion entitled "Cardiac Emergencies."

Subcommittee on Temporary Voluntary Reporting

At an early date, the Cardiac Program Committee felt the need for an inventory of the cardiac problem in Newton. The vital statistics of the health department and the hospital records have been studied in an attempt to determine the amount

of heart disease in the community and the relative importance of the various types. However, it was believed that information more pertinent to program planning might be obtained if private physicians were to report cardiac cases.

To test the value of such a procedure, for a three-month period the members of the Cardiac Program Committee and the subcommittee are reporting their cardiac cases to the health department. Besides data concerning the disease the reporting form is designed to indicate the extent of the need for such supplementary services as nutrition and rehabilitation.

Subcommittee on Community Organization

As in all public-health projects success of the Newton Heart Program will depend to a great extent upon support by the public. An interested well informed citizenry is not enough. They should actually participate by helping to implement some of the nonmedical aspects of the program.

Plans are being studied for developing an organization representing all interested agencies, clubs and people of Newton. As a first step in this direction an inservice education program has been carried on for community health and welfare personnel. The Heart Demonstration Program has twice conducted a course in "The Public Health Aspect of Heart Disease" to help these workers become more familiar with cardiac problems. Members of the Cardiac Program Committee, as well as Boston cardiologists and public-health leaders have appeared as speakers.

Subcommittee on Nutrition

The importance of special diets in the treatment of heart disease⁵ suggested possibilities for a community nutrition program. A small study has been started to determine methods of approach and consider the problems involved.

Instruction is being given by the nutritionist of the demonstration unit under the supervision of the attending physician. Patients referred for reduction, low-sodium and rice diets are included.

From a careful appraisal of the results of this study, it is hoped to develop procedures for providing some part of this service through group meetings, public-health nurses and other available community resources.

Subcommittee on Rehabilitation

The Cardiac Program Committee believed that rehabilitation represented one of the most challenging fields for action. Providing diversional activities during the period of convalescence, helping the patient resume his duties in the home and, perhaps most important, assisting him to return to a productive job will contribute to his mental well being and, therefore, to recovery. Certainly in this phase of the program, widest use will be made of exist-

ing community agencies and of such state agencies as the Department of Vocational Rehabilitation. The Subcommittee on Rehabilitation has recommended the addition of a trained worker to the staff of the demonstration unit to assist in developing the possibilities of this program. Action has been delayed pending his arrival.

The activities undertaken so far are regarded only as a beginning. They represent some of the more obvious needs that must be met to improve the status of the cardiac and the potential cardiac patient. Frankly experimental, they may be changed and adjusted with time and experience.

FUTURE PLANS FOR THE PROGRAM

Additional problems of cardiac patients are being studied. Programs for prevention, for medical salvage and for case finding are under consideration.

Prevention

Prevention offers the greatest hope. By prevention we mean measures taken to delay heart disease and prevent complications. The Cardiac Program Committee is especially concerned with the need for a weight-control program, prophylaxis of subacute bacterial endocarditis and prophylaxis of rheumatic fever.

Weight Control

Obesity after middle age shortens life expectancy.⁶ The Subcommittee on Nutrition is concerned with the part excessive weight plays in the causation of heart disease, and has given a weight-control program a high priority in its plans. However, the Subcommittee has a profound respect for the difficulties of achieving results by public-health methods. The problem is threefold: the prevention of obesity, reduction of those who are overweight and maintenance of ideal weight after reduction. The problem of weight control is almost as difficult as that of keeping an alcoholic patient sober. In fact, the technics of Alcoholics Anonymous are being studied to determine if any are applicable to control of obesity.

Since there are many dangers of obesity and the person seeking to lose weight may be sick, medical supervision will be an important part of a weight-control program.

Subacute Bacterial Endocarditis

Although subacute bacterial endocarditis accounts for a relatively small percentage of cardiac cases, its importance from a public-health standpoint is enhanced now that it can be successfully treated and apparently even prevented.⁷ Prevention often depends on the use of prophylactic drugs for all patients with valvular and congenital heart disease undergoing any oral operative procedure and even dental prophylaxis. The Cardiac Program Committee and the Newton Dental Society are

therefore planning a co-operative study of the problem. A joint committee has been established to recommend methods by which physicians and dentists of Newton can help prevent subacute bacterial endocarditis.

Rheumatic Fever

Prevention of recurrences of rheumatic fever during the months of hemolytic-streptococcus infection has been placed on the agenda for future study. The Committee plans to determine the extent to which prophylaxis of rheumatic fever is used and would also like to determine to what extent school physicians are aiding in case finding of rheumatic fever. It is hoped that, in attempts to make preventive measures available, not only encouragement but also active support can be given to public agencies and private physicians responsible for children who have had rheumatic fever.⁸

Medical Salvage

Our future program must also consider facilities in the community for meeting unsolved problems in diagnosis and treatment. The committee hopes to help develop and extend resources that can aid the physician in diagnosis and treatment. These include, among others, the cardiac clinic and agencies doing public-health nursing and medical social work.

Cardiac clinic The cardiac clinic, operated by the outpatient department of the hospital, can be one of the most effective aids of a community heart program. Standards for cardiac clinics have been developed by the New York Heart Association and adopted by the American Heart Association. It is the belief of the association that the cardiac clinic should serve as a center for physician education, and as a clinic for the diagnosis and treatment of indigent persons. The committee hopes to help develop and strengthen the local cardiac clinic to carry out the functions recommended by the American Heart Association.

Public-health nursing As the activities of the heart program become more numerous, there will be greater dependence upon the work of the public-health nurse. She can play a significant role by rendering bedside nursing care in the home, by referring potential cardiac cases for diagnosis, by interpreting, at the physician's request, diagnosis and treatment, by following lapsed cases for referral back to physicians or clinic, and by directing patients to community agencies for needed services.

Two nurses, with special training in heart disease, have been included in the demonstration unit. They will help the general staff nurses of the health department and the District Nursing Association to develop an awareness of the cardiac problem.

Medical social work Medical social activities of the hospital, clinic or welfare agency, carried on

under the advice and guidance of physicians, can be of help to cardiac patients in every stage of their illness. The availability of case-work services to patient and family may help to eliminate many of the hazards of long-term illness. Such a service will be encouraged as the Newton Heart Program begins to develop its activities further.

Case Finding

Since there is a growing optimism about the results to be obtained through early treatment of heart disease, one of the chief concerns of the Cardiac Program Committee is to get possible cardiac patients to their physicians for early diagnosis. One answer, of course, is to encourage periodic physical examinations by physicians, and this will be done. But it is often difficult to persuade people to see their physicians so long as they are well, and many physicians find that the time available for periodic examination of healthy people is limited by the demands of those who are ill.

Solution of the problem may be found in a screening method that will permit the examination of well people and the referral of suspected cases to their private physicians. Possibilities are being studied by a subcommittee.

Individuals vary in their likelihood for developing heart disease. It has been shown⁹ that, when neither parent has hypertension, only 3 per cent of the offspring of such parents were found to be hypertensive. However, when both parents were so affected, 45 per cent of the offspring were found with hypertension. There are similar leads in rheumatic heart disease and coronary-artery disease.

Perhaps the people who are most likely to develop heart disease should be shown that they require more frequent checkups from their physicians. We are studying the possibility of devising a chart to show each person the extent of his heart hazards. In this way, our limited resources for case finding may be directed where they are most needed.

Many of the plans of the Newton Heart Program are based upon recent developments in the field of

cardiology. It can safely be said that a program of this sort is possible today only because of these new developments. However, many more measures are needed before a significant reduction in heart disease in the productive ages can be achieved. We look to the research field to provide us with the tools.

If the medical and public-health professions have a program in operation that can effectively apply preventive and salvage measures as they are unearthed, the time lag between laboratory discoveries and protection and healing can be reduced.

SUMMARY

An interim report of the Newton Heart Demonstration Program is presented.

The aims of this program are to analyze the extent of the heart-disease problem in a local community, to analyze the present unsatisfied needs of the potential and actual heart patient in the community, to evaluate the possible role of public-health and other local agencies in meeting these needs, to obtain total physician participation in the program and encourage ever-increasing improvement in the quality of medical care, to help develop a permanent all-out effort against the No. 1 killer of Americans.

A review of the efforts to date is presented.

THE RELATION OF CAVITY TO THE DEVELOPMENT OF STREPTOMYCIN-RESISTANT TUBERCLE BACILLI IN PULMONARY TUBERCULOSIS*

ROGER S MITCHELL, M D †

TRUDEAU, NEW YORK

IT IS increasingly apparent that the usefulness of streptomycin therapy in pulmonary tuberculosis is seriously limited by the frequent and often early appearance of tubercle bacilli that are resistant† to the drug. The development of this resistance in vitro has been observed to coincide with loss of effectiveness of the drug in vivo¹⁻⁴

The incidence of streptomycin resistance has been found to increase with the number of days that treatment is given^{1, 3, 5, 7}. It is believed, in addition, that resistant strains appear earlier and more frequently in patients with severe constitutional symptoms and in those with extensive pulmonary involvement^{4, 5}. On the other hand, the development of resistance apparently bears no relation either to the size of the daily dose of the drug or to the frequency of its administration during the day⁶.

That the development of streptomycin resistance may be a serious complication is made painfully clear to the clinician who no longer has available its remarkably beneficial therapeutic effect for coincident use in resectional surgery, or for the treatment of a serious, acute pneumonic spread of disease.

The temptation to use the drug in chronic pulmonary tuberculosis, however, remains strong. This is not only because of the unpredictable and striking benefit occasionally seen but also because the tubercle bacilli of a small number of patients unaccountably fail to develop resistance even if the patients are treated for four months or more.

This study was originally suggested by the finding of a considerably lower incidence of streptomycin resistance in patients at Trudeau Sanatorium (Table 1) than in patients being treated elsewhere⁵. The difference was made more significant by the fact that the same criteria and methods for determining streptomycin resistance⁷ were used in the two series. It was further noted that streptomycin-resistant tubercle bacilli were only rarely recovered from patients who showed no roentgenographic evidence of pulmonary cavity before streptomycin treatment.

This report is a critical analysis of these data in an effort to discover whether a relation exists be-

tween cavity and the development of streptomycin resistance.

MATERIALS AND METHODS

The material for this study consists of all the 117 patients§ treated with streptomycin¶ between November, 1946, and December, 1948, from whom adequate sputum specimens|| were obtained during and after completion of streptomycin therapy. In 6 patients a second course of streptomycin given from six to eighteen months after the first course was arbitrarily considered a separate case, making 123 cases in all. The two courses given to each of these 6 patients were considered individually regarding the duration of therapy. There were only 116 cases studied, since 7 were excluded from analysis because of certain indications for use of the drug, as follows: during and after pneumonectomy, 1, tuberculous bronchiectasis, 3, and tuberculous empyema, 3.

The indications for streptomycin in the 116 cases studied were progressive pulmonary tuberculosis, 98, endobronchial tuberculosis without cavity, 14, tuberculous laryngitis, 2, and intestinal tuberculosis, 2.

All patients had active pulmonary tuberculosis, and the sputum in all 116 cases was positive before therapy. Plaingrams were widely used to determine the presence and extent of cavity. Treatment of 16 cases was begun before admission to the sanatorium. In each of the other 100 cases in which treatment was initiated at the sanatorium or at Saranac Lake, sputum cultures obtained before therapy revealed strains of tubercle bacilli that were sensitive to streptomycin. Very small numbers of tubercle bacilli, natively resistant to low dilutions of streptomycin before treatment, are disregarded for the purposes of this study.

The daily dose of streptomycin in this series varied from 0.5 to 2.0 gm per day, but was usually 1 gm per day. The drug was given in two daily intramuscular injections at twelve-hour intervals in almost every case.

The method of sputum concentration, culture and inoculation of mediums containing varying dilu-

cases in which resistant organisms for each of the various durations of therapy developed is shown, the numbers in each group are too small to justify the use of percentages.

In Table 2 the incidence of streptomycin resistance in 3 classes of patients is recorded.

When cavity was present before therapy and no satisfactory collapse measure was applied coincidentally, streptomycin resistance was found in 20 (40 per cent) of 51 cases with positive cultures at the end of treatment. Nine of these 20 showed organisms resistant to 1000 microgm of streptomycin per cubic centimeter of medium.

When no cavity was present before therapy, drug resistance had developed in 3 (11 per cent) of 29

20 cases with positive cultures at the end of treatment.

The highest degree of resistance attained by any of the 5 cases showing resistance in the last two groups was to 60 microgm of drug per cubic centimeter of medium.

It is of interest that in 14 cases treated primarily for endobronchial disease without cavity and having positive cultures at the end of therapy, drug resistance occurred in only 1 (7.3 per cent). The mean duration of streptomycin therapy in these 14 cases was two and seven-tenths months.

The significance of the notable differences in incidence of resistance in the three groups is open to question, since there was not only a wide varia-

tion in duration of therapy in individual cases (Table 1) but also a moderate difference in the mean durations of therapy (Table 2).

The relation of incidence of resistance to duration of therapy in pulmonary tuberculosis has been de-

‡Resistant organisms were also recovered from 2 out of the 5 cases of old empyema not included in this study.

§Satisfactory collapse measures used were as follows: thoracoplasty 12 cases, pneumothorax 3 cases, pneumoperitoneum 7 cases, and pneumoperitoneum with phrenicoplasty 3 cases.

terminated by several investigators. The Veterans Administration has reported the largest experience so far.⁶ Only an insignificant difference was found in the incidence of resistance in patients treated for one hundred and twenty days with 0.5, 1.0, 1.8 or 2.0 gm per day. Table 3 summarizes their findings in 1030 patients so treated. The incidence of drug resistance in 46 patients treated at the Veterans Administration Hospital in Sunmount, New York, and determined at the Trudeau Laboratory⁷ rather closely paralleled these findings. The observations of others have been similar.²⁻⁵

Each case in the three groups of Table 2 was then assigned an individual chance of developing resistance, on the basis of the percentages in Table 3, for example, resistance is predicted in 24 per cent of those receiving treatment for one month and is

TABLE 3 *Relation of Duration of Daily Streptomycin Treatment (0.5 to 2.0 gm) to the Incidence of Development of Drug Resistance**

therefore predicted in 24 out of 100, 0.24 out of 1, 0.48 out of 2 and so forth. The decimal numbers of cases of resistance predicted in each group were totaled, divided by the number in the group and then converted from a decimal back to a percentage. The chance of resistance predicted in this way on the basis of duration of therapy was found to be approximately the same for each group — 48, 49 and 42 per cent, respectively. Therefore, the difference in the actual incidences observed — 40 per cent in the first group, 11 per cent in the second and 10 per cent in the third — is considered to have a significance not materially influenced by variations in duration of therapy.

The size of cavity present before therapy also bore a numerical relation to the incidence of development of resistance in this series. Cavity was measured roughly as the total average roentgenographic diameter of all cavities in both lungs. Of 55 patients with cavity before therapy, 51 still had positive cultures after therapy. Resistance developed in 12 per cent of 8 cases with cavities of 1 cm or less, in 33 per cent of 27 cases with cavities of 1.5 to 3 cm and in 63 per cent of 16 cases with cavitation of 3.5 cm or more. The mean duration of therapy varied from two and one-tenth to two and two-tenths months in these three groups.

There were 45 cases in which cavities failed to disappear during streptomycin treatment. The tubercle

bacilli recovered in 24 of these remained drug sensitive, those in the other 21 developed resistance. Although the cases developing resistance tended to have had more extensive cavitation and more severe constitutional symptoms than those retaining sensitivity, it must be emphasized that there were certain notable exceptions.

DISCUSSION

These findings are in accord with the observations of Howlett and O'Connor,⁸ who reported that streptomycin resistance developed in only 1 of 15 patients treated for a chronic disseminated nodular type of pulmonary tuberculosis. Further experience to date⁹ supports their view that "resistance occurs more commonly in patients with frank caseation or persistent cavity."

The mechanism of streptomycin resistance is not clear. The observations in this series and those of Howlett and O'Connor suggest that the amount of caseation may have an important bearing on the phenomenon. Resistance is theoretically more likely to develop when bacilli are exposed to low concentrations of the drug. Such a low concentration could be due either to the impaired blood supply in caseous tissue or to the presence of excessive numbers of bacilli, or to both.

Streptomycin-resistant tubercle bacilli have been recovered after treatment in some cases of miliary tuberculosis^{6, 10} and tuberculous meningitis^{10, 11} in which there was no demonstrable cavitation. In these cases, however, there was usually pathological evidence of a grossly caseous focus near a blood vessel, which had presumably given rise to the dissemination.

Both sensitive and resistant organisms have been recovered at autopsy from different parts of the body and even from different foci in one lung.¹² There may therefore be justifiable doubt that the tubercle bacilli isolated from a patient at any one time are truly representative of all the organisms infecting the host. In this connection, it is also possible that collapse traps secretions containing tubercle bacilli of a state of sensitivity or resistance differing from those contained in material reaching the laboratory from other parts of the lung.

When sputum cultures become repeatedly negative before termination of drug therapy, the *in vitro* reaction to streptomycin of the tubercle bacilli still within the body is also unknown. Streptomycin-resistant tubercle bacilli have occasionally been recovered for the first time from cultures again found positive some months after turning negative.¹³ When cultures of the collected material had become repeatedly negative in 16 cases of this series, there was a coincident clinical arrest of the disease. In addition, all positive cultures obtained before sputum conversion in these 16 cases revealed sensitive organisms.

The exact level of streptomycin resistance at which a serious interference with the clinical effectiveness of the drug occurs is still not clearly established. There is no longer much doubt, however, that *in vitro* resistance to streptomycin is to be avoided at all costs, if possible. Nevertheless, at times it may be poor judgment to fail to use the drug because of this fear when there is indication for the drug and a reasonable chance of lasting benefit. This will be true without reservation when the clinician or bacteriologist is able to select the cases in which drug resistance is most unlikely to develop. This study suggests that careful selection of cases for drug therapy may significantly reduce the risk of drug resistance in chronic pulmonary tuberculosis.

Perhaps a more important, though less well documented, observation is the use of collapse measures coincident with streptomycin therapy to reduce the risk of drug resistance. Others have already suggested that streptomycin be used to prepare the patient for collapse therapy.^{13, 14} In certain situations, especially in the treatment of acute pneumonic or rapidly progressing lesions, this approach appears sound in spite of the risk of development of resistance. When pneumothorax is planned and tuberculosis of the smaller bronchi is suspected, or when bronchoscopy is not available in a suspicious case, a two-week or three-week course of streptomycin before collapse may reduce pneumothorax complications.

If the experience of others confirms the findings of this study, however, it appears logical to withhold streptomycin, whenever possible, until collapse is well established and is having a satisfactory relaxing effect on the cavity-bearing lung. This course is sound when one considers how long it often takes to establish a suitable collapse, and how quickly drug resistance sometimes supervenes. Pneumothorax may lead to one or more thoracoscopies, pneumopentoneum may require the addition of phrenicosis or vice versa, more stages of thoracoplasty may be required than originally planned, and, finally, two or more different collapse measures may have to be tried because of mechanical failure of the measure first chosen. If streptomycin is given first or coincident with the beginning of the first collapse measure employed the usual

forty-two-day to sixty-day course of the drug may well be completed and the bacilli may have become resistant before collapse is mechanically satisfactory.

With increasing knowledge of the advantages and limitations of both streptomycin and collapse in chronic cavitary pulmonary tuberculosis, it is no longer always rational to try each method separately. In the light of these observations, coincident utilization of the mechanical effects of collapse and the immunologic benefits of streptomycin should be seriously considered.

SUMMARY

In a series of 116 patients treated with streptomycin at Trudeau Sanatorium positive sputum or gastric cultures were obtained from 100 at some time after therapy was completed. In these 100 cases *in vitro* resistance to the drug developed as follows: in 40 per cent of 51 with pretreatment roentgenographic evidence of cavity and no coincident collapse, in 11 per cent of 29 without cavity before therapy, and in 10 per cent of 20 with cavity before therapy but with a coincident satisfactory collapse measure.

The possible explanation and clinical significance of these observations are discussed.

MEDICAL PROGRESS

CHILD HEALTH SERVICES IN MASSACHUSETTS

JAMES MARVIN BATY, M D,* AND LENDON SNEDEKER, M D, M P H †

BOSTON

THE American Academy of Pediatrics has completed a nation-wide study of health services for children. The findings were published by the Commonwealth Fund in April of this year, and have already led to action to improve the health of the nation's children. The study originated in 1944 when the Committee on Post-War Planning reported to the membership of the Academy on the general situation regarding the health of the country's children and recommended that a survey of existing health services be made before any future health program was undertaken. At the same time legislation was pending in Congress that threatened radically to change the nature of medical practice. The study was to ascertain the extent and distribution of present services to children whether provided by professional men in practice, by hospitals and clinics, or by voluntary and official community health agencies.

The Academy study began in North Carolina in the fall of 1945. Other state studies were started in the spring of 1946, following procedures set by the Committee for the Study of Child Health Services, with a central office under the leadership of Dr. John P. Hubbard, the executive director. The results of these studies are now being published in most of the states and recommendations are being made regarding future action, state by state, in the light of local conditions.

This effort is striking evidence of the collective concern of the physicians and dentists of the country for the welfare of children. It is the first time that doctors have pooled their voluntary efforts and inquired into the facilities serving the nation's child population. The survey was made by those directly responsible for rendering health service, and the recommendations are based on facts viewed in the light of a knowledge of local conditions within the states.

In the development of the survey it was left to the initiative of each state chairman to develop an organization in his state, make plans for the distribution and collection of schedules, finance the work and arrange for the reporting of the findings. The central office was responsible for setting the procedures to be followed, for tabulating the data and for returning information to the states for their own use.

*Professor of pediatrics, Tufts College Medical School, president Massachusetts Chapter, American Academy of Pediatrics.
†Executive secretary, Massachusetts Study of Child Health Services.

The Massachusetts study corroborates and emphasizes some of the national findings of the Academy. The importance of the general practitioner in caring for children and the uneven distribution of medical services are both apparent. In Massachusetts, as in the country generally, three fourths of the private medical care of children is supplied by general practitioners. They take care of most of the sick children and also, as a group, do most of the well-child supervision.

Massachusetts, in common with most of the New England states, possesses certain characteristics that set it off from the rest of the country. The population is older. Per-capita incomes are high. There are many small and independent agencies serving children, and official health activities are administered by the local city or town rather than by the county.

MASSACHUSETTS STUDY

The Massachusetts Study of Child Health Services was organized in the spring of 1946 and its report, of which this article is a digest, has recently been published by the American Academy of Arts and Sciences ‡.

In tabulating data and for comparing sectional differences in health service the Academy study has compiled its information by county and by "metropolitan character of county." This statistical device, which classifies counties according to both population density and proximity to centers of population, is of less use in Massachusetts, where there are only fourteen counties and the population is more uniformly distributed than elsewhere. There are only three "isolated" counties in the Commonwealth: Barnstable, Dukes and Nantucket. Comparatively rural areas in several other counties are obscured (Fig. 1). For this reason Massachusetts data have also been tabulated by health districts, since these seem more adequately to bring out variations in service. Furthermore, they correspond to the present administrative areas of the Massachusetts Department of Public Health (Fig. 2).

Detailed information regarding the collection of data for the Massachusetts study will be found in the complete report to which reference has already been made.

‡American Academy of Arts and Sciences, *Health Services for Massachusetts Children*. Special publication 1949.

Massachusetts is the twelfth wealthiest state in the Union, with an average annual per capita income of \$1289, but in 1946 the Commonwealth ranked twenty-second in maternal mortality and twentieth in infant mortality among the states (Table 1) Boston its largest city, had an infant mortality one

marized report, but the salient points are briefly outlined, together with selected supporting data

Total of Medical and Dental Service for Children

Massachusetts ranks third in the country with respect to the total amount of medical service that

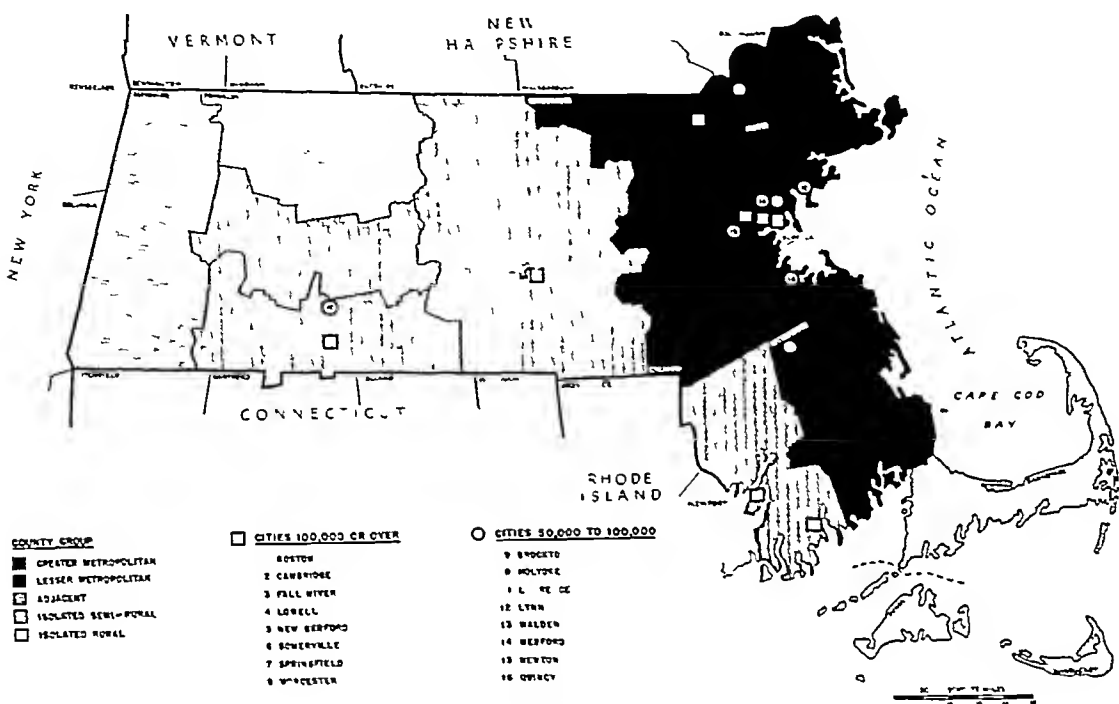

FIGURE 1 County Groups in Massachusetts

point higher than the national average (34.8 per thousand live births)

Massachusetts has an aging population. A third of the inhabitants of the United States, but only a fourth of those in Massachusetts, are under the age of fifteen years.

The Commonwealth has many fewer children living in rural areas than in the rest of the country. Thirty-seven per cent of those in the United States but only 11 per cent of the children in Massachusetts live in "isolated counties."

Responsibility for the maintenance of most official public-health services for children rests with the 351 cities and towns in the Commonwealth. Many of these are small municipalities financially incapable of supporting adequate, modern, full-time health services. Although this multiplicity of governmental units preserves independence and local autonomy, it results in inadequate financing, supervision and integration of health activities.

The findings of the Massachusetts study cannot all be compressed into the confines of this sum-

marized report. The rate of medical care is exceeded only by that in Nevada and New York.

FIGURE 2 Health Districts in Massachusetts

Three fourths of the total consists in visits to children by medical practitioners (Fig 3). Out of a total of 20.3 children per day per 1000 children under

MEDICAL PROGRESS

CHILD HEALTH SERVICES IN MASSACHUSETTS

JAMES MARVIN BATY, M.D.,* AND LENDON SNEDEKER, M.D., M.P.H.†

BOSTON

THE American Academy of Pediatrics has completed a nation-wide study of health services for children. The findings were published by the Commonwealth Fund in April of this year, and have already led to action to improve the health of the nation's children. The study originated in 1944 when the Committee on Post-War Planning reported to the membership of the Academy on the general situation regarding the health of the country's children and recommended that a survey of existing health services be made before any future health program was undertaken. At the same time legislation was pending in Congress that threatened radically to change the nature of medical practice. The study was to ascertain the extent and distribution of present services to children whether provided by professional men in practice, by hospitals and clinics, or by voluntary and official community health agencies.

The Academy study began in North Carolina in the fall of 1945. The Massachusetts study corroborates and emphasizes some of the national findings of the Academy. The importance of the general practitioner in caring for children and the uneven distribution of medical services are both apparent. In Massachusetts, as in the country generally, three fourths of the private medical care of children is supplied by general practitioners. They take care of most of the sick children and also, as a group, do most of the well-child supervision.

Massachusetts, in common with most of the New England states, possesses certain characteristics that set it off from the rest of the country. The population is older. Per-capita incomes are high. There are many small and independent agencies serving children, and official health activities are administered by the local city or town rather than by the county.

MASSACHUSETTS STUDY

The Massachusetts Study of Child Health Services was organized in the spring of 1946 and its report, of which this article is a digest, has recently been published by the American Academy of Arts and Sciences.†

In tabulating data and for comparing sectional differences in health service the Academy study has compiled its information by county and by "metropolitan character of county." This statistical device, which classifies counties according to both population density and proximity to centers of population, is of less use in Massachusetts, where there are only fourteen counties and the population is more uniformly distributed than elsewhere. There are only three "isolated" counties in the Commonwealth: Barnstable, Dukes and Nantucket. Comparatively rural areas in several other counties are obscured (Fig. 1). For this reason Massachusetts data have also been tabulated by health districts, since these seem more adequately to bring out variations in service. Furthermore, they correspond to the present administrative areas of the Massachusetts Department of Public Health (Fig. 2).

Detailed information regarding the collection of data for the Massachusetts study will be found in the complete report to which reference has already been made.

†American Academy of Arts and Sciences, *Health Services for Massachusetts Children*. Special publication, 1949.

amounted to 4.06 child visits per physician, or 20.1 child visits per 1000 children per day. General practitioners made three quarters of these visits.

Care to children constitutes almost a third of the practice of the general practitioner. Of 18,984 visits to patients of all ages, 30.8 per cent were made to children under the age of fifteen.

About a third of all general practitioners do major surgical operations on their child patients, half do

Place of Health Supervision in Medical Service to Children

Health supervision constitutes nearly a third of the medical service given to children. In addition to furnishing health service in private practice, doctors participate in various types of community health service.

For the whole United States 26 per cent of the child care provided by the general practitioner is for

tonsillectomies, and four fifths are consulted for advice regarding problems in infant feeding.

Ratio of Pediatricians to General Practitioners

Massachusetts ranks fifth among the states in the number of children per pediatrician. There is 1 pediatrician for every 5360 children, as compared with one for 10,299 in the United States.

Pediatricians are younger than the run of practitioners. The median age for pediatricians in Massa-

health supervision. Over twice this amount is furnished by pediatricians (54 per cent). In Massachusetts general practitioners devote 33 per cent and pediatricians 62 per cent of their time with children to health service (Fig. 5).

The doctor is also actively engaged in various types of community health services. Of 1259 phy-

FIGURE 4 Rates for Total Medical Service by Health District in Massachusetts, Expressed as Children under Care per Day per 1000 Children

chusetts is forty-five years. Sixty-six per cent of general practitioners and 76 per cent of pediatricians are under the age of fifty-five years.

Ninety-seven per cent of the 180 pediatricians registered by the Massachusetts Study were located in cities of over 10,000 population.

FIGURE 5 Proportion of Practice Devoted to the Care of Well and Sick Children by General Practitioners and Pediatricians in Massachusetts (Average Number of Visits per Day)

cians reporting, 13 per cent had worked in well-child conferences during the month preceding the survey, and about an equal number had worked with school health services.

Hospital Privileges for Care of Children

Hospital privileges for the care of children are restricted for a fifth of practitioners. Nineteen per cent of 1597 physicians reporting said that they were not permitted to care for their child patients in the nearest hospital admitting children.

medical care, 151 were visited by physicians in their homes or visited a doctor's office

There are over twice as many children in Massachusetts under dental care as there are in the whole

Proportion of Medical Service for Health Supervision

About 30 per cent of the children under care on an average day are receiving health supervision Two

†Other than Massachusetts for percentage of children in isolated counties

United States There are 7.2 children per 1000 children under care on an average day, compared with 3.3 per 1000 for the whole country Nine

thirds of this is furnished by the general practitioner Well-child conferences account for about one tenth of all health supervision

Distribution of Medical and Dental Care

Children in the three "isolated" counties (Barnstable, Dukes and Nantucket) receive two thirds as much pediatric care, one third as much specialist care, one fifth as much clinic care and about half as much hospital service as their fellows in the other counties of the Commonwealth Similarly, the rate for dental care is lower in these isolated counties (5.6 per 1000, contrasted with 7.4 per 1000 for metropolitan and adjacent counties)

If medical care is considered by health district it is clear that children in Districts 1 and 5 receive the lowest rates of service (Fig 4)

Distribution of Physicians and Dentists

Massachusetts ranks second among the states with reference to the number of physicians in private practice There is 1 physician for every 855 people, and 1 for every 202 children under the age of fifteen Of all practitioners, 61 per cent are family doctors, 4 per cent are pediatricians, and 35 per cent are specialists in other fields Ninety per cent of medical practitioners live in cities with populations of 10,000 or more, which contain 83.5 per cent of the inhabitants of the Commonwealth There are fewer doctors in Districts 1, 2 and 6 in proportion to the child population

Massachusetts ranks fifth with respect to the number of dental practitioners There is 1 dentist for every 368 children Over 90 per cent of dentists live in cities of 10,000 or more The proportion of dentists to population in District 3 is twice that in Districts 1 and 6

Contribution of General Practitioner to the Care of Children

On an average day the physicians in Massachusetts made a total of 19,418 visits to children This

FIGURE 3 Total Volume of Medical Care for Children on One Day per 1000 Children in Massachusetts Comparison with the United States and Selected States

tenths of the dental care to children is furnished by dental practitioners, and one tenth by dental clinics The comparative figures on medical and dental service are shown in Table 2

than half of these have separate pediatric clinics. There is only one hospital outpatient department in the "isolated" counties (Barnstable, Dukes and Nantucket). Clinic facilities are less in Districts 2, 5, 7 and 8. Special pediatric clinics are almost all located in the more urban areas.

Care in Dental Clinics

The rate of dental-clinic care of children is high in Massachusetts, but there is considerable difference in the rates of care in the various health districts.

Children in the neighborhood of Metropolitan Boston (District 3) receive much more care than those in other districts, whether this is expressed in terms of dentist hours, patients, visits or examinations. Official dental agencies care for more children, but provide less service to the individual child.

Distribution of Public-Health Nursing Service

Although Massachusetts ranks fourth among the states in the amount of public-health nursing service to children, there are inequalities in the distribution of service and a need to increase the proportion of nurses who have had specialized training.

Fifty-nine per cent of the cities and towns in the Commonwealth reported that they maintained some form of public-health nursing service. The distribution of nurses in the state is uneven, and the rates for service vary. There are often several nursing agencies in a single city or town without provision for co-ordination of effort. Only a small percentage of nurses have had special training in public health. Of 854 nurses 686, or 80 per cent, had had no formal training in a recognized program of public-health nursing, or had completed less than one academic year.

Character of Medical Service for School Children

Some kind of medical service is almost universally available to the school children of Massachusetts, but there is great variation in the character of that service. Although there are no counties without school health supervision, seven towns fail to report any service. Eighty-eight per cent of the physicians in the public schools are general practitioners. Only 47 of 602 school physicians are pediatricians. Less than half the 552 school nurses reported are employed full time.

Health Supervision for Children of Pre-school Age

Massachusetts ranks second among the states in the amount of health supervision for children of pre-school age. About one tenth of such care is provided by well-child conferences.

The rates of care for well-child conferences (Fig. 6) are not uniform and are lowest in Health Districts 4 and 5. Over half the 276 well-child conferences reported are maintained in whole or in part by official agencies. Children make an average of two and eight-tenths visits per year each. In a few towns conferences are held only twice a year.

General practitioners and pediatricians together provide about four fifths of the medical service at these clinics. Most of them are part-time, paid workers. Five per cent of the general practitioners and 13 per cent of the pediatricians serve without compensation.

Service in Well-Child Conferences

There is considerable variation in the kind of service available in well-child conferences. Infants receive more care than older children. Practically all clinics provide nursing service, and medical advice regarding feeding and child management is

FIGURE 6 Yearly Rates per 1000 Children for Three Types of Community Health Service in Massachusetts by Health District. Well-child conference visits are expressed per 1000 children under five years of age.

available at 83 per cent of all sessions. Approximately two thirds of the sessions provide nutrition service, and one fifth psychologic or psychiatric advice when needed.

Immunization in Well-Child Conferences

Well-child conferences are not effective in immunizing children against communicable disease. Only a small percentage of sessions routinely provide immunization. One third immunize against diphtheria, whooping cough and smallpox. In clinics where the number of children immunized is known, slightly less than half the children are vaccinated and about one quarter immunized against diphtheria and whooping cough. The practices followed in various clinics are not uniform and often fail to recognize the need for immunization in the first two years of life, rather than in the pre-school period.

Care of Physically Handicapped Children

Facilities for the care of the physically handicapped are fairly evenly distributed throughout the Commonwealth. A large amount of specialized orthopedic and other care to physically handicapped children is provided in hospitals, especially in the teaching centers of Boston, and is not enumerated by the study. Clinics maintained under the Crippled Children's Program limit their services to children

Inadequacies in Hospital and Pediatric Training

The considerable proportion of practice concerned with the medical problems of children and degree of responsibility assumed by the practitioner for the surgical problems of childhood calls for adequate pediatric training. Although the preparation of physicians for practice is continually improving, it is noteworthy that of 1607 general practitioners in Massachusetts 72 per cent reported that they had had no hospital training whatever. A total of 25 per cent had had less than a year of training. Over a third had had less than a month's hospital work in pediatrics before entering practice, and slightly less than a third had had no postgraduate training in pediatrics. Doctors who had had more than a year of hospital training were making 85 per cent of the visits to children.

Deficiencies in the Training of Dental Practitioners

Only half the 1735 dentists reporting had had any training in children's dentistry. Training in the care of children was more frequently reported by older practitioners.

Hospital Facilities for Children in the State as a Whole

The Commonwealth is fifth in number of hospital beds, third in number of children's beds and ninth in the number of child admissions per 1000 children. One twentieth of the 43,084 general-hospital beds for children in the United States are in Massachusetts. Total hospital beds in Massachusetts number 18.2 per 1000 children, and children's beds 2.2 per 1000.

There are 151 general hospitals in the Commonwealth, 140 of which admit children. There are 72 hospitals with pediatric units of 5 or more beds, and 3 pediatric hospitals. More than half the pediatric beds are located within a 25-mile radius of Boston.

Nonprofit hospitals provide nearly three quarters of the available beds for children. Municipal hospitals, with 23.4 per cent of the pediatric beds, care for only 14.2 per cent of the child admissions.

Hospital Facilities for Children in Rural Areas

There are 11.6 general-hospital beds per 1000 children in the "isolated" counties (Barnstable, Dukes and Nantucket), and 18.3 per 1000 in the rest of the State. There are only a quarter of the pediatric beds in isolated counties in proportion to the child population that there are in the State as a whole. There are fewer hospital facilities for children in Districts 1, 2 and 4.

Size of Hospital

Most children are admitted to large general hospitals with over 100 beds, especially to those with pediatric units, 73.9 per cent of all child admissions occur in hospitals with more than 100 beds, and 86 per cent in hospitals with pediatric units.

Use of Pediatric Beds

Pediatric beds are not fully utilized. The occupancy rate for pediatric beds in the Commonwealth averages 60 per cent, but rates as low as 45 per cent have been noted for certain hospitals.

Effect of Size and Character of Hospitals on Quality of Care

Hospital facilities for children improve with size, and hospitals with pediatric units are more adequately staffed and equipped. Small proprietary hospitals are limited in laboratory facilities and trained personnel for the management of pediatric cases.

Isolation Facilities for Infants and Graduate-Nursing Supervision

Thirty-one per cent of child admissions occur in hospitals with no graduate nurse in charge of the pediatric unit. In 36 per cent infants, other than newborn, are not segregated from older children, and the risk of intercurrent infections is correspondingly greater.

Births in Hospitals

In 1946, 97.2 per cent of the births in Massachusetts occurred in hospitals. The percentage was slightly lower in the isolated counties (89.7) and nonwhite mothers had slightly more births outside hospitals in the same area. The average length of hospital stay for newborn infants was nine and four-tenths days.

Neonatal Infection

Certain conditions in newborn nurseries predispose to neonatal infection.

Twenty-three per cent of the births in Massachusetts hospitals during the report year occurred in hospitals without a separate formula room, and 45 per cent in hospitals lacking isolation facilities for sick infants or for those suspected of being ill.

Care of Mentally Sick, Mentally Deficient and Epileptic Children

Two thirds of the facilities for the convalescent and chronic care of children are reserved for the care of mentally sick, the mentally deficient and epileptic patients. Waiting lists in institutions caring for such children are very long, and the amount of supervision by graduate nurses is far less than that in other institutions caring for the chronically sick.

Care in Medical Clinics

The rate of clinic care of children is high in Massachusetts, being twice that for the United States average. However, clinics account for only 5 per cent of all medical service to children.

Eighty per cent of all the clinics caring for children are in general hospitals of over 100 beds, and more

in his own office. Modern transportation reduces the necessity for providing a variety of outpatient services, but the poor, who are in greatest need of corrective services, are least able to travel. Programs for the correction of physical defects will continue to be relatively ineffective and unnecessarily expensive as long as diagnostic and corrective services are inconveniently distant from the affected child.

A few general points might be made regarding community health services for children. Well-child conferences cannot be considered really effective until they provide the medically indigent with continuously accessible facilities for examination, immunization and medical advice. An average of two and eight-tenths visits per year is not enough to constitute regular health supervision. The average well-child conference is not effective in immunizing children against the important communicable diseases. Although these conferences should not be the only agencies providing immunization, they should be more effective with the clientele they serve. At present the diversity of health agencies, their physical separation and the resultant partition of medical service discourage the medically indigent from seeking attention. It would be advantageous to centralize health services more often and to locate them, where possible, in or near the local hospital.

If towns wish to maintain their own services, there should be some provision for unification and supervision of their work. One or more adequately paid pediatric consultants could do much to improve the present situation. The solution of many child health problems would be facilitated if agencies were working more often in conjunction with local health units of adequate size, and employing well trained, full-time personnel.

RECOMMENDATIONS

In consideration of the large proportion of medical practice that is concerned with children, medical schools should devote more attention to maternal and child health in their curriculums, placing emphasis on preventive technics applicable in private practice.

In addition to their present educational activities, the Massachusetts Medical Society, the Massachusetts Chapter of the American Academy of Pediatrics and the New England Pediatric Society should sponsor programs for training in maternal and child health for all professional persons caring for children, with particular emphasis upon those preparing for general practice.

Dental schools should likewise stress preventive dentistry and its application to childhood in their curriculums. Research should include an energetic inquiry into methods of dental prophylaxis. Where dental personnel is inadequate greater use of auxiliary personnel should be considered.

Means should be found for encouraging young physicians to settle in the parts of the Commonwealth where children are now receiving less than the average amount of medical service.

Wherever possible hospital privileges should be extended to physicians who show an active interest in increasing their professional ability by availing themselves of opportunities for postgraduate education.

The present co-operative efforts of the Massachusetts Medical Society and the Massachusetts Department of Public Health to reduce maternal mortality should be intensified. Some investigation of infant deaths should be undertaken. The present system for reporting infant births and deaths, especially those among premature infants, needs improving.

Local hospitals should increase their existing safeguards against cross infection in children's wards and nurseries for newborn infants. Adequate isolation facilities are of major importance.

Construction of new hospital facilities for children should be undertaken only after due study of local needs and the present utilization of existing beds. The limitations of the community hospital in treating the diseases of children and its function as a health center deserve reconsideration.

The Massachusetts Department of Public Health should be enabled to provide pediatric, nursing and other consultants to work on the problem of correlating and improving local health work for children.

Present facilities for the hospital care of children with mental deficiency and convulsive disorders should be increased.

Well-child conferences should increase the frequency of their health supervision and intensify their efforts to detect and follow children with defects. The efficiency of the present immunization program should be improved and present policies should be scrutinized. Opportunities should be increased for the training of doctors conducting well-child conferences.

Dental clinics in the Commonwealth should be increased in areas where present services are below average.

Public-health nursing services should be more adequately supervised and integrated. Under present conditions service is unevenly distributed, and there is too much opportunity for duplication of effort. Standards for the employment and training of public-health nursing personnel need improving.

The medical and dental professions should give support to the recommendations made in the *Report of the Special Commission to Study and Investigate Certain Public Health Matters* (House Document 2100, 1949). Those having special importance are the development of local full-time health services, improvement in present methods for collecting and transmitting vital statistics, and the provision of adequate standards of employment and remuneration for public-health personnel.

with orthopedic and plastic conditions, and to those with speech defects

Care of Mentally Handicapped Children

The existing services for mentally handicapped children are too limited. There are 21 mental-hygiene clinics operated by the Massachusetts Department of Mental Health or the city of Boston. There are only 3 independent clinics under voluntary auspices, and 7 voluntary hospitals with special mental-hygiene facilities. All the clinics have complete staff service, which means at least a part-time psychiatrist, a psychologist and a social worker. Nearly two thirds of the clinics have a full-time psychiatrist in attendance.

DISCUSSION

The foregoing summary gives abundant evidence of the high standard of medical care now provided for Massachusetts children. However, a large number of doctors and dentists, a high rate for health supervision and a large percentage of births in hospitals have not produced an exceptionally low mortality or a great reduction in dental decay, and have not been effective in immunizing a large percentage of the children attending well-child conferences. The twelfth wealthiest state in the Union should not stand in twentieth place in infant mortality or twenty-second in maternal death rate. Although it is agreed that such rates are not the only measure of the efficacy of a health program, one does not expect a highly urban state such as Massachusetts to be outstripped by rural states like Nebraska and North Dakota, or by such nearly comparable neighbors as Rhode Island and Connecticut. These mortality rates seem unnecessarily high.

Medical care for children in Massachusetts, as well as in the rest of the United States, is unevenly distributed and least available in rural areas. In view of the small proportion of children living in the isolated counties of Massachusetts, this may not be as significant as in other states, where the problems of distance make it difficult to obtain medical service. However, such inequalities need investigating, and will have to be eliminated before it can be said that all children in the Commonwealth have an equal chance to survive infancy and grow to competent majority.

The general practitioner, who is by far the most important person providing medical service to children, needs more pediatric training, both in medical school and in hospital. In the realm of postgraduate pediatric education, a review of programs sponsored by the Massachusetts Medical Society or by the New England Postgraduate Assembly discloses relatively few papers dealing with the problems of children. This is by no means meant as a reflection on the very considerable program now being carried out by the Society, in co-operation with the Massachusetts Department of Public Health, both at weekly sessions held for two months

each year in Boston and at the meetings of its district medical societies.

There is another opportunity for improving the pediatric education of physicians. It was noted that nearly a fifth of physicians lacked hospital privileges in near-by institutions to which their child patients were admitted. With further means developed for including these physicians in the educational activities of these hospitals and with the elimination of substandard medical schools, eventually more doctors should be able to enjoy hospital privileges.

What has been said of physicians is equally true of dental practitioners. The small number of dentists who specialize in children's work or in orthodontia is evidence of the relative lack of interest in the dental problems of early life. With the dentists now available, or in prospect, it is practically impossible to meet present demands for restorative dental work, even if the means could be found to pay for it. It is probably advisable to extend the use of auxiliary dental personnel, but especially to develop effective mass prophylaxis against dental decay.

Hospital facilities for children are unevenly distributed throughout the Commonwealth. Part of this inequality may be compensated for by the transportation of sick children to suitable pediatric centers, but the situation calls for some critical consideration. It is not only a lack of beds but also the manner in which they are utilized and safeguarded that is important. About a third of the hospitals admitting children have no graduate nursing supervision of their pediatric beds. There is evidence that some hospitals lack adequate provision for safeguarding infants, including newborn, against intercurrent infection in the hospital. There is evidence that pediatric beds are not being fully utilized. Construction of new beds for children should probably not be undertaken until it is clear that present use is optimal. These are matters that should be considered and, when necessary, improved through the local action of practitioners interested in the welfare of children. The Division of Hospitals of the Massachusetts Department of Public Health is an important factor in improving hospital standards. It should be sufficiently provided with personnel so that it is able to temper its present regulatory power with a large amount of educational work. More often hospital standards should be based on the collective experience of practicing physicians, and this is well exemplified by the recent report of the Committee on the Fetus and Newborn of the American Academy of Pediatrics.

The prime need in the field of chronic care is to provide more beds for the mentally deficient and epileptic.

Outpatient facilities are fewer in the isolated areas of the Commonwealth. On the other hand the practitioner in the country runs his own outpatient department along with his practice. A relative lack of clinics may be chiefly important in the diagnostic facilities that the average physician cannot provide.

in his own office. Modern transportation reduces the necessity for providing a variety of outpatient services, but the poor, who are in greatest need of corrective services, are least able to travel. Programs for the correction of physical defects will continue to be relatively ineffective and unnecessarily expensive as long as diagnostic and corrective services are inconveniently distant from the affected child.

A few general points might be made regarding community health services for children. A relative lack of clinics may be chiefly important in the diagnostic facilities that the average physician cannot provide.

time of examination two weeks later, however. Five weeks before entry he was admitted to another hospital and treated with aerosol penicillin. During a four-week period of hospitalization the symptoms increased in severity. At home, during the week prior to readmission to this hospital, ankle swelling appeared, and dyspnea became very marked.

Physical examination showed a well nourished man, who was coughing and dyspneic. There was no venous distention in the neck. The anteroposterior diameter of the chest was increased. The chest was hyperresonant, except at the right base. Diffuse rhonchi were heard throughout. Breath sounds were decreased at the right base. Auricular fibrillation was present, with an apical rate of 100 and a pulse rate of 80. The first heart sound at the apex had a snapping quality. The pulmonic second sound was louder than the aortic. No murmurs were heard. The blood pressure was 125 systolic, 90 diastolic.

The white-cell count was 12,000, with a normal differential. The hemoglobin was 15 gm. The urine had a specific gravity of 1.020 and gave ++ to +++ tests for albumin, and there were rare red and white blood cells in the sediment. The sedimentation rate was 19 mm. per minute. The stools were brown, and the guaiac test was ++. Sputum cultures were repeatedly negative for beta-hemolytic streptococci and pneumococci. Repeated blood cultures were negative.

An electrocardiogram showed a coarse auricular fibrillation and right-axis deviation. Chest x-ray study revealed an enlarged heart shadow and moderate congestion in both lungs. There was some fluid present at the right base. No atelectasis was seen.

During the hospital stay the patient ran a low-grade fever, ranging between 99 and 102°F. Dyspnea and cough, accompanied by blood-streaked sputum, persisted. Therapy included digitalis, aerosol penicillin and mercurhydrin. After three weeks in the hospital there was no improvement. Marked weakness developed. Chemical examination of the blood at this time showed a nonprotein nitrogen of 34 mg. per 100 cc., and a sodium of 110.6, chloride of 70 and carbon dioxide of 29.2 milliequiv. per liter. Vigorous therapy with salt by mouth (2 gm. and more daily) resulted in no improvement. The highest serum sodium obtained was 114.1 and the highest chloride 75 milliequiv. per liter.

He complained of severe abdominal discomfort and persistent anorexia. Extreme weakness continued. The liver was enlarged and tender. Five weeks after readmission he became unresponsive. The pulse became unobtainable and over a period of two hours the respirations gradually slowed and ceased.

DIFFERENTIAL DIAGNOSIS

DR. CONGER WILLIAMS: Nothing is said about cyanosis so I assume that it was not present. In view of the complexity and length of this account, I might pause and consider briefly a few possibilities.

This is a middle-aged man who came in with

a history of cough for ten years, dyspnea for eight years and an important cardiac arrhythmia—namely, auricular fibrillation. In a man of this age a very common cause of auricular fibrillation is mitral stenosis, especially with a history of this length. Could mitral stenosis alone account for such a long history of cough and dyspnea? It could, but there are two points that must be mentioned, which perhaps are a little against mitral stenosis as the only cause for his symptoms: the amount of productive sputum that the patient had over a period of several years and the severity of the cough. These two reservations suggest another possibility,—chronic pulmonary disease, either as the only lesion or complicating mitral stenosis. It is quite conceivable that he had the syndrome of chronic bronchitis, emphysema and asthma over many years. I cannot tell from the physical examination reported whether the chest showed the structural changes expected in such a situation.

DR. HELEN PITTMAN: We thought it did.

DR. WILLIAMS: So perhaps that possibility is a little stronger. It was mentioned earlier in the history that this patient worked in a steel mill twenty years before admission, where he was exposed to large amounts of metal dust. This brings up the possibility of pneumoconiosis, but I can do nothing more than suggest the possibility since there was no known exposure to silica or asbestos. Did this man have enough pulmonary disease to give him chronic heart disease, namely, chronic cor pulmonale, which, complicated by auricular fibrillation, might account for congestive failure? Auricular fibrillation as a complication of cor pulmonale, especially at this age, is unusual but not impossible. Another thing that seems quite evident is that regardless of the cause of the chronic symptoms, he had an acute infection, possibly in the lungs, since he had chills just before entry, and fever and leukocytosis in the hospital. It is possible that he had pneumonia, complicating old chronic pulmonary infection.

If the red-cell count of 6,700,000 represents a real polycythemia, that finding is in favor of chronic pulmonary disease. We do not very often see polycythemia in heart disease unless there is a right-to-left shunt. However, this may not have been real polycythemia, but merely a result of hemoconcentration from fever, profuse sweating and so forth. I do not believe that congestive failure, although quite marked, could account entirely for the +++ test for albumin in the urine, but it is possible. Rusty sputum goes with either a chronic or an acute history of pulmonary involvement. It is possible that the nephrotic syndrome was suspected at this time, judging from some of the tests done. Either of the bromsulfalein figures could be consistent with various degrees of congestive heart failure.

After examination of the electrocardiogram and observation of the chest leads, it is more evident that he had right ventricular enlargement. The

CASE 35381

PRESENTATION OF CASE

First admission A forty-one-year-old Italian shoemaker was admitted to the hospital complaining of a cold in the chest.

For ten years before admission the patient had a severe cough, which increased in frequency and severity up to admission. Eight years before entry dyspnea appeared, especially after bouts of coughing. A chest x-ray examination was said to have demonstrated some "bronchial difficulty, but no serious disease." Five years before admission the dyspnea had become so severe that he was forced to take an easier job at which he could sit down. Two years before entry, on the advice of his physician, digitalis was started and maintained up to admission. There had been no weight loss. There was an inconclusive history of one or two slight episodes of ankle edema. He had had night sweats for many years. Orthopnea requiring three pillows at night was present for three years. A cupful of dark-brown, nonfoul-smelling sputum was raised every day. Four days before admission he "caught a cold in his chest" and had two severe chills during which his teeth chattered. The cough increased in severity, and he felt feverish.

He had worked in a steel mill twenty years before admission and was exposed to large amounts of metal dust and fumes but not to silica.

Physical examination showed a well developed man, breathing quickly with an audible wheeze. The heart was slightly enlarged to the left and moderately enlarged to the right. The rhythm was that of a rapid auricular fibrillation, with an apical rate of 130 and a radial pulse rate of 80. Numerous sibilant and musical rales and increased tactile fremitus were present over the right posterior chest. The liver edge extended four or five fingerbreadths below the costal margin and was smooth and tender. The fingers were not noticeably clubbed, but the nails were extremely curved. The temperature was 102°F.

Examination of the blood revealed a white-cell count of 15,000, with 78 per cent neutrophils. The hemoglobin was 17 gm., and the red-cell count

and gave a +++ test for albumin, and there were occasional red and white blood cells in the sediment. The sputum was rusty and negative for acid-fast organisms. The stools were guaiac negative. The prothrombin time was 23 seconds (control, 18 seconds). The van den Bergh test was 12 mg per 100 cc direct and 20 mg indirect. The total protein was 7.42 gm per 100 cc, with an albumin of 3.49 gm and a globulin of 3.93 gm (albumin-globulin ratio of 0.89). The cephalin-flocculation test was + in forty-eight hours. The cholesterol was 263 mg, the nonprotein nitrogen 34 mg, and the serum phosphorus 2.8 mg per 100 cc. The alkaline phosphatase was 3 units. A bromsulfalein test showed 22 per cent retention and 8 per cent retention on separate occasions. An electrocardiogram demonstrated auricular fibrillation, with a ventricular rate of 160. Right-axis deviation was present. The T wave in Lead 1 was flat. The ST segments in Lead 2 and 3 were sagging, and the T waves in Lead CF₁, CF₂, and CF₃ were inverted. The S waves in the precordial leads were of greater voltage than normal. The vital capacity was 1.7 liters. X-ray study of the chest demonstrated an enlarged heart without any characteristic configuration, the ratio being 15.7 to 32.2. There was considerable engorgement of the hilar and pulmonary blood vessels. There was a diffuse, hazy increase of density in the left lower chest, with a small amount of fluid in the left pleural cavity.

Digitalis, small doses of quinidine and intramuscular administration of penicillin had no remarkable therapeutic effect. When aerosol penicillin was given the temperature gradually subsided, and the severity of the cough and sputum production diminished. He was discharged one month after admission.

Final admission (three years later) He was followed regularly in the Out-Patient Department. During the entire interval between admissions therapy included digitalis, ammonium chloride and a low-salt diet. Auricular fibrillation was present at each examination. For the first two years he was able to do light work, although exertional dyspnea and orthopnea were marked. In the year before readmission weakness, cough and exertional dyspnea were so great that he was unable to work, spending much of his time in bed. There was no ankle edema. Two and a half years before re-entry on one examination, with the apex rate at 84 and with the patient in the left lateral recumbent position, the first heart sound was sharp, and a distant, rumbling, mid-diastolic murmur was noted. Chest x-ray examination showed no appreciable change in heart size and configuration, although it was evident that the left auricle was enlarged. The lung fields were clear. At intervals carious teeth were extracted while the patient received penicillin intramuscularly. About three months before readmission he complained of several episodes of bloody sputum and a tender swelling in the left leg. There was no tenderness or swelling at

CLINICAL DIAGNOSES

Cardiac insufficiency
Rheumatic heart disease, active
Pulmonary emphysema

DR WILLIAMS'S DIAGNOSES

Rheumatic heart disease mitral stenosis, auricular fibrillation, congestive failure
Chronic bronchitis
Pulmonary embolism?

ANATOMICAL DIAGNOSES

Rheumatic heart disease, with mitral stenosis
Multiple pulmonary embolism and infarction, massive, old and recent
Cardiac hypertrophy, right ventricle (cor pulmonale)
Massive mural thrombus, left auricle, obliterating mitral valve and extending into pulmonary vein
Hydrothorax, right
Central necrosis of liver

PATHOLOGICAL DISCUSSION

DR BENJAMIN CASTLEMAN The autopsy was limited to the chest, unfortunately I cannot answer some of the abdominal questions. We were able to examine a piece of liver and found marked central necrosis. The right pleural cavity contained 3 liters of rather clear fluid.

The startling gross finding was the presence of infarcts of various ages in every lobe of the lung. Most were located in the right lower lobe, one of which was apparently fairly old and had a central necrotic abscess in it, which is very unusual in a bland pulmonary infarct. This infarct was the largest, measuring 8 cm in diameter, with a central cavity of 3 or 4 cm. Although we were unable to find on the gross examination any infarcts that seemed completely healed, we did find in some of the arteries within the lung evidence of old embolism with recanalization, some involving the tiny arteries. Some of the larger vessels had adherent thrombi that were perhaps a year or so old. So it is quite possible that a great deal of the right-sided hypertrophy was due to old embolism of the lung. There was some emphysema but not very much fibrosis of the lung.

The heart was enlarged, weighing about 500 mg, most of the enlargement being due to right-sided hypertrophy. The right ventricle measured 10 mm in thickness, three or four times the normal size, and the right auricle was tremendously distended, much more than the left, which was also dilated. This was surprising, at first glance, because there was severe mitral stenosis. Filling the large left auricle and obliterating the already stenotic mitral valve was a huge mural thrombus, 8 by 5 by 4 cm. The large mural thrombus not only filled the left auricle but extended into the pulmonary vein from the right lower lobe, and since there were many emboli in the pulmonary artery to this lobe, there was probably very little blood getting in and out, thus accounting for the cavitation in the large infarct.

DR WILLIAMS Was that recent?

DR CASTLEMAN It must have been there for some time, because it was adherent and well organized, perhaps for months. We have therefore a number of possibilities to account for the large right ventricle: some emphysema, a severe mitral stenosis, and embolism, both chronic and recent, occurring in the pulmonary circuit.

DR ALFRED KRANES What was the source of the pulmonary emboli?

DR CASTLEMAN I suppose from the leg veins. We were unable to examine them, but we know that there was a phlebitis clinically.

DR CHAPMAN Could they not have come from the right auricle?

DR CASTLEMAN No, there was no mural thrombus in the right. There is the possibility that atherosclerosis of the pulmonary arteries, which occurs with mitral stenosis, may have initiated the formation of small thrombi. I have always believed, however, that pulmonary thrombosis rarely occurs and that most of the lesions in the pulmonary circuit are emboli rather than local thrombi.

CASE 35382

PRESENTATION OF CASE

A seventy-five-year-old nulliparous widow was admitted to the hospital because of vomiting and abdominal pain.

In the two years prior to admission the patient had been "below par" and had lost 25 pounds. For one year she had had progressive constipation, passing small, hard stools occasionally mixed with blood. Two days before admission she noted obstipation, cramping lower abdominal pain and vomiting of all ingested material. There was no fecal return from several enemas, and various laxatives taken were vomited.

The past history included a right radical mastectomy for carcinoma twenty years previously and a total hysterectomy and salpingo-oophorectomy for cancer of the uterine fundus twelve years before admission. The appendix was said not to have been removed. The patient had noted anginal chest pain on exertion for five years, with occasional nocturnal dyspnea, and had been taking digitalis up to one month prior to admission.

Physical examination showed a dehydrated, elderly woman. The heart was enlarged to percussion. A rough systolic murmur transmitted into the neck was heard in the aortic area, and there were systolic and presystolic murmurs at the apex. The abdomen was distended, somewhat rigid, and showed rebound tenderness referred to both lower quadrants. There was tenderness in both vaginal vaults and some fullness more on the right. An indistinctly outlined mass was felt in the right lower quadrant.

The temperature was 102°F, the pulse 100, and the respirations 24. The blood pressure was 110 systolic, 70 diastolic.

pattern is very characteristic I think cor pulmonale, congenital heart disease and mitral stenosis are the most likely possibilities

May we see the x-ray films? The earlier films might have been helpful, but we do not have them. Do you see anything that suggests long-standing pulmonary disease or congestion on a vascular basis?

DR STANLEY M WYMAN The pattern in the lung shows first of all enlarged hilar shadows. I take them to be engorged vessels. The peripheral vascular findings and the fluid in the right pleural space and probably to a slight degree in the left, perhaps in an interlobar fissure, suggest pulmonary congestion and cardiac decompensation. I cannot say whether these peripheral nodular changes are acute or chronic on this one film, but they disappear later except for a few small nodules that remain out in the periphery of the left lung.

DR WILLIAMS Do you wish to comment on the possibility of mitral stenosis?

DR WYMAN I think the films are good evidence for an enlarged left auricle seen through the heart. These two films outline the left main bronchus and form a double contour as seen on the right of the heart. That is also seen to some degree on the lateral projection. I cannot comment on the ventricular enlargement, but it could be left or right.

DR WILLIAMS Do you think the prominence of the pulmonary artery would account for that?

DR WYMAN I do not believe it could account for all of it, surely, it could not give a double contour of the auricle through the heart.

DR WILLIAMS Apparently this picture gradually subsided.

The mid-diastolic murmur is, of course, helpful in the diagnosis of mitral stenosis. On the other hand, it is well to recall that ventricular dilatation alone may produce a mid-diastolic rumble. The patient had auricular fibrillation, so no presystolic murmur could be heard. "Auricular fibrillation was present at each examination." This recurring statement is quite important.

The tender swelling in the leg three months before admission may have been important, and made me wonder whether pulmonary embolism, which is a common complication in a history of this kind, had at last appeared.

The positive guaiac reaction made me wonder whether the patient had been swallowing bloody sputum or whether he had had a mesenteric embolus secondary to long-standing auricular fibrillation. It is evident from the repeated blood cultures that the diagnosis of subacute bacterial endocarditis was entertained at this time, but no evidence for it was found. I think it is likely that the low-salt diet accounted in this case for weakness as it does in so many others.

Anorexia may have been due to the distended liver or some lesion in the abdomen such as a mesenteric lesion.

To sum up rapidly, I am quite sure that this patient had mitral stenosis, whatever else he may have

had. I probably feel that way because of the early onset and persistence of auricular fibrillation in a man of forty-two at the time of the first hospital admission. Also, the x-ray pictures and the electrocardiogram are both in keeping. However, I do not believe that mitral stenosis accounts for everything.

At autopsy, I should not be surprised to find evidence of chronic bronchial disease or emphysema or possibly pulmonary fibrosis. Did he have subacute bacterial endocarditis? It is possible that he did. There was a history of teeth extractions, although they were covered by penicillin in each instance.

One other thing we ought to consider in a patient who has had peripheral venous congestion so long is constrictive pericarditis. Among many objections to this diagnosis is the proportion of dyspnea to other symptoms. It is true that many patients with constrictive pericarditis also have dyspnea but certainly not to this extent, nor are they troubled by cough as this patient was.

So for my principal diagnosis, I will say that this man had mitral stenosis, with rheumatic heart disease, and chronic bronchitis. I disregard the possibility of congenital heart disease because right-axis deviation in the absence of cyanosis does not fit in with the x-ray picture. It is remotely conceivable that he had auricular septal defect, but I doubt it. We have seen an occasional case of patent ductus arteriosus with nothing but a mitral rumble and without the usual characteristic murmurs. However, I dismiss this possibility. I considered the possibility of amyloidosis to account for the renal picture, which somewhat approaches that of the nephrotic syndrome. This does remain a possibility. I cannot very well account for it on any other grounds. I do not believe he had chronic nephritis. He maintained a good urine concentration throughout the illness. Many cases discussed at these conferences turn up with unexpected acute glomerulonephritis at autopsy, but there is no evidence for it here.

DR HOWARD B SPRAGUE You have to include the possibility of reactivation of rheumatic fever, do you not?

DR WILLIAMS I meant to mention it. I should not be surprised to find Aschoff bodies in the myocardium. It is quite possible that the patient died in active rheumatic fever.

DR EARLE M CHAPMAN Would you include the possibility of pulmonary infarction?

DR WILLIAMS No, but I would not be surprised to find small pulmonary emboli at autopsy.

DR SPRAGUE I saw the patient on his original entry and for some time followed him in the Out-Patient Department. The problem was considered to be cor pulmonale. I turned him on his side one day and found that he had a sharp aortic first sound and a mitral diastolic rumble. I am on record as saying that he had mitral stenosis, so I will stand or fall on that.

cardiac mural thrombus was thrown off to the mesenteric artery. She could have had thrombosis on the venous side, with infarction of a small area of bowel. It is conceivable that this could produce a temporary intestinal obstruction, that the viability of that part of the bowel would be in doubt for some days and then that circulation would be re-established by way of collateral vessels later. Then, perhaps, on the sixteenth day in the hospital a fresh venous thrombus occurred, possibly a massive thrombosis of the mesenteric or even the portal vein caused the vomiting of fresh blood and the passing of blood by rectum. In fact, a high thrombosis of the mesenteric vein is the only way I can explain bleeding from both the upper and the lower intestinal tract, so I am going to make this my diagnosis.

I might say something about the prothrombin time. It was 48 per cent of normal on admission. That suggests one of two things to me: liver disease or malnutrition. There is nothing in the protocol that suggests liver disease so I am going to say it was due to malnutrition. It is not at all uncommon for a woman or man over seventy to lose weight, to lose appetite and stop eating and to become chronically dehydrated. This may be the explanation for the weight loss and constipation, rather than a chronic malignant lesion of the bowel.

DR JOHN W RAKER: When this woman came into the Emergency Ward most of the people who saw her preferred a diagnosis of perforated appendix, with appendiceal abscess. We called the hospital where she was operated on previously, and it was definitely ascertained that the appendix was left behind according to the hospital record. It was our opinion at the time of admission that she was too ill to stand an operation, although there was considerable discussion about it. We thought she had a certain amount of congestive failure as well as dehydration. There was evidence that something was localizing in the right lower quadrant. We followed her on a conservative regime for five days and began to think that we might drain her through the right lower quadrant. The symptoms subsided spontaneously with the appearance of foul stools, and we thought perhaps she had drained herself into the bowel. We waited in the hope that we could reach the stage where we could safely operate on her. The electrocardiogram showed the findings recorded. We were never able to explain why she was bleeding, although we persisted to the end in our belief that she probably had a perforated appendix.

DR TRACY B MALLORY: There must have been some consideration of carcinoma of the cecum because that was the written diagnosis on the death report.

DR RAKER: I believe the majority of people who saw her favored the diagnosis of appendiceal abscess. There was a minority in favor of carcinoma of the cecum, and the doctor who signed the death report must have belonged to that minority.

CLINICAL DIAGNOSIS

Appendiceal abscess?

Carcinoma of cecum?

DR HARWOOD'S DIAGNOSIS

Mesenteric thrombosis

ANATOMICAL DIAGNOSES

Abdominal abscess

Generalized peritonitis

Jejunioileal fistula

Anterior myocardial infarct, recent

Duodenal ulcers, active

Aneurysm of descending aorta

PATHOLOGICAL DISCUSSION

DR MALLORY: The autopsy findings were rather puzzling, and I do not feel entirely satisfied that we can explain everything we found. She had a large intra-abdominal abscess, and the stump of the appendix projected into this abscess. It was only 1 cm in length and was densely fibrous and had no lumen. It would be rather unusual for an appendix of that type—that is, an obliterated appendix—to perforate, and we could find nothing that we could recognize as necrotic portions of the appendix. As the autopsy was continued we found that there was a fistulous tract between the jejunum, about 20 cm below the ligament of Treitz, and one of the lower loops of the ileum, and this fistula was in immediate approximation with the intra-abdominal abscess, so that leakage could have occurred through that. The walls of the fistula were slightly inflamed and thickened. There was no evidence of neoplasm, tuberculosis or any specific infection. The origin and nature of that lesion, I cannot explain. How long this fistula had been present, we are unable to say, and whether it or the appendix was the source of the abdominal abscess also has to remain a doubtful question.

She also had a severe arteriosclerotic heart disease, with numerous spots of marked narrowing of the left descending coronary artery and a focus of fresh infarction, a little over 2 cm in diameter, in the interventricular septum. An incidental finding was an arteriosclerotic aneurysm of the abdominal aorta containing a mural thrombus.

DR RAKER: Was not something found in the duodenum?

DR MALLORY: There were two acute peptic ulcers in the duodenum that accounted for the vomiting of blood. We did explain that.

A PHYSICIAN: Another possibility to explain that bleeding is acute pancreatitis.

DR MALLORY: The pancreas showed only interstitial edema, such as one commonly sees in a case with peritoneal infection.

A PHYSICIAN: Was there dissection in the aneurysm?

DR MALLORY: No, it was a simple pouch-like arteriosclerotic aneurysm.

Laboratory studies showed a normal urine. The hemoglobin was 13.5 gm per 100 cc, and the white-cell count was 12,950. The stools gave a ++ guaiac reaction on two occasions. The nonprotein nitrogen was 44 mg, and the total protein 6.3 gm per 100 cc, the serum chloride 104 milliequiv per liter, and the prothrombin time 48 per cent of normal. Vaginal smears showed no neoplastic cells. Plain films of the abdomen showed gas-filled loops of small and large bowel. Chest x-ray films confirmed the cardiac enlargement.

A Miller-Abbott tube was inserted, and a transfusion of 500 cc of whole blood administered. The patient was started on intravenous injection of fluids, penicillin, streptomycin, Digalen and opiates. Peristalsis was audible, and she occasionally passed gas by rectum. However the temperature and white-cell count remained elevated and the urinary output was very low. On the seventh day the pulse rate rose to 210, and an electrocardiogram showed auriculoventricular dissociation. Tachycardia was incompletely controlled by quinidine. The right-lower-quadrant mass seemed to decrease in size, as did a fullness in the right vault on the eighth day, when foul, liquid bowel movements began. Active normal peristalsis was heard at this time, and for five days she tolerated liquids by mouth with the Miller-Abbott tube out. On the sixteenth day she began to vomit fresh blood and coffee-grounds material and to pass fresh clots by rectum. The blood pressure fell to 80 systolic, 60 diastolic, and the patient complained of anginal pain.

Transfusion of 1000 cc of whole blood produced some clinical improvement, but on the morning of the eighteenth day she suddenly became disoriented, the heart beat and respirations ceased, and she was pronounced dead.

DIFFERENTIAL DIAGNOSIS

DR REED HARWOOD: May we see the x-ray films?

DR JAMES A. McCORT: The x-ray examination was limited to a plain film of the abdomen. The tip of a Miller-Abbott tube is present in the fundus of the stomach. Distal to the stomach there are at least two dilated loops of small bowel. Air is present in the ascending colon. There may also be a small amount of air in the descending colon and sigmoid. The mass described in the protocol is not visible on the x-ray film.

DR HARWOOD: Is that a pressure defect?

DR McCORT: There is not a sufficient amount of air in the cecum for me to be certain.

DR HARWOOD: The history, then, is one of intestinal obstruction that relieved itself after eight days in the hospital. Ten days later the patient vomited fresh blood and also passed fresh blood by rectum and rapidly went into shock and died.

I am first going to present a list of conditions that I think we should consider, with a comment on each: metastatic carcinoma or recurrence of one of the previous carcinomas, a new carcinoma

of the colon or a tumor of the ileum, with intussusception, and tuberculosis of the cecum, diverticulitis and mesenteric thrombosis.

Regarding metastatic carcinoma, the patient had two previous operations for carcinoma in the past. The first one was twenty years before admission, when her breast was removed, and the other was for carcinoma of the uterine fundus twelve years previously. It seems to me that the objection to postulating recurrence of metastasis from either of these two primary tumors is the duration since the tumor was removed. We know that occasionally there is a late recurrence of carcinoma. In both cases, I would expect a recurrence to appear either in the lungs, the liver or the bone marrow. Therefore, I am excluding metastatic carcinoma.

We know from previous exercises that it is not at all uncommon for a patient to have two or three carcinomas in different organs of the body. Perhaps this patient had a predisposition for the formation of malignant tumors. The history is good for carcinoma of the bowel. She had chronic constipation and a down-hill course for over a period of two years, with increasing constipation, finally ending in obstruction. The physical findings are consistent with such a diagnosis. We know with carcinoma of the right colon that the typical history is alternating periods of constipation and diarrhea, but there is no suggestion that she had diarrhea in the past two years. The obstruction was relieved in this case, and I should not expect that to occur in carcinoma that has slowly encircled the lumen of the cecum or ascending colon. Tumor of the ileum with intussusception and intussusception from a tumor in the region of the cecum are both possibilities that are attractive because of the fact that after eight days in the hospital the obstruction was relieved and she passed foul, liquid bowel movements. I would rather expect this patient to have been much sicker, possibly in shock, with a much higher white-cell count if she had had intussusception on admission.

Tuberculosis of the cecum can cause both bleeding and obstruction. I think it is unlikely in this case because of the absence of any suggestion of tuberculosis in the lung.

Diverticulitis, possibly with abscess formation and discharge of the contents of the abscess into the lumen of the bowel, might possibly explain the relief of obstruction in this case. Diverticulitis is much more common in the left colon than in the right. I merely mention this as a possibility, I cannot prove it.

Finally, we come to a consideration of mesenteric thrombosis, venous or arterial. If arterial, it could have been the result of arteriosclerosis of the mesenteric arteries or an embolus from some other source. We know, for example, that the patient had arteriosclerotic heart disease, and it is possible, although I think unlikely, that she had had a coronary occlusion in the recent past and an embolus from a

cardiac mural thrombus was thrown off to the mesenteric artery. She could have had thrombosis on the venous side, with infarction of a small area of bowel. It is conceivable that this could produce a temporary intestinal obstruction, that the viability of that part of the bowel would be in doubt for some days and then that circulation would be re-established by way of collateral vessels later. Then, perhaps on the sixteenth day in the hospital a fresh venous thrombus occurred, possibly a massive thrombosis of the mesenteric or even the portal vein caused the vomiting of fresh blood and the passing of blood by rectum. In fact, a high thrombosis of the mesenteric vein is the only way I can explain bleeding from both the upper and the lower intestinal tract, so I am going to make this my diagnosis.

I might say something about the prothrombin time. It was 48 per cent of normal on admission. That suggests one of two things to me: liver disease or malnutrition. There is nothing in the protocol that suggests liver disease so I am going to say it was due to malnutrition. It is not at all uncommon for a woman or man over seventy to lose weight, to lose appetite and stop eating and to become chronically dehydrated. This may be the explanation for the weight loss and constipation, rather than a chronic malignant lesion of the bowel.

DR JOHN W. RAKER: When this woman came into the Emergency Ward most of the people who saw her preferred a diagnosis of perforated appendix, with appendiceal abscess. We called the hospital where she was operated on previously, and it was definitely ascertained that the appendix was left behind according to the hospital record. It was our opinion at the time of admission that she was too ill to stand an operation, although there was considerable discussion about it. We thought she had a certain amount of congestive failure as well as dehydration. There was evidence that something was localizing in the right lower quadrant. We followed her on a conservative regime for five days and began to think that we might drain her through the right lower quadrant. The symptoms subsided spontaneously with the appearance of foul stools, and we thought perhaps she had drained herself into the bowel. We waited in the hope that we could reach the stage where we could safely operate on her. The electrocardiogram showed the findings recorded. We were never able to explain why she was bleeding, although we persisted to the end in our belief that she probably had a perforated appendix.

DR TRACY B. MALLORY: There must have been some consideration of carcinoma of the cecum because that was the written diagnosis on the death report.

DR RAKER: I believe the majority of people who saw her favored the diagnosis of appendiceal abscess. There was a minority in favor of carcinoma of the cecum, and the doctor who signed the death report must have belonged to that minority.

PATHOLOGICAL DISCUSSION

DR MALLORY: The autopsy findings were rather puzzling, and I do not feel entirely satisfied that we can explain everything we found. She had a large intra-abdominal abscess, and the stump of the appendix projected into this abscess. It was only 1 cm. in length and was densely fibrous and had no lumen. It would be rather unusual for an appendix of that type—that is, an obliterated appendix—to perforate, and we could find nothing that we could recognize as necrotic portions of the appendix. As the autopsy was continued we found that there was a fistulous tract between the jejunum, about 20 cm. below the ligament of Treitz, and one of the lower loops of the ileum, and this fistula was in immediate approximation with the intra-abdominal abscess, so that leakage could have occurred through that. The walls of the fistula were slightly inflamed and thickened. There was no evidence of neoplasm, tuberculosis or any specific infection. The origin and nature of that lesion, I cannot explain. How long this fistula had been present, we are unable to say, and whether it or the appendix was the source of the abdominal abscess also has to remain a doubtful question.

She also had a severe arteriosclerotic heart disease, with numerous spots of marked narrowing of the left descending coronary artery and a focus of fresh infarction, a little over 2 cm. in diameter, in the interventricular septum. An incidental finding was an arteriosclerotic aneurysm of the abdominal aorta containing a mural thrombus.

DR RAKER: Was not something found in the duodenum?

DR MALLORY: There were two acute peptic ulcers in the duodenum that accounted for the vomiting of blood. We did explain that.

A PHYSICIAN: Another possibility to explain that bleeding is acute pancreatitis.

DR MALLORY: The pancreas showed only interstitial edema, such as one commonly sees in a case with peritoneal infection.

A PHYSICIAN: Was there dissection in the aneurysm?

DR MALLORY: No, it was a simple pouch-like arteriosclerotic aneurysm.

Laboratory studies showed a normal urine. The hemoglobin was 13.5 gm per 100 cc, and the white-cell count was 12,950. The stools gave a ++ guaiac reaction on two occasions. The nonprotein nitrogen was 44 mg, and the total protein 6.3 gm per 100 cc, the serum chloride 104 milliequiv per liter, and the prothrombin time 48 per cent of normal. Vaginal smears showed no neoplastic cells. Plain films of the abdomen showed gas-filled loops of small and large bowel. Chest x-ray films confirmed the cardiac enlargement.

A Miller-Abbott tube was inserted, and a transfusion of 500 cc of whole blood administered. The patient was started on intravenous injection of fluids, penicillin, streptomycin, Digalen and opiates. Peristalsis was audible, and she occasionally passed gas by rectum. However the temperature and white-cell count remained elevated and the urinary output was very low. On the seventh day the pulse rate rose to 210, and an electrocardiogram showed auriculoventricular dissociation. Tachycardia was incompletely controlled by quinidine. The right-lower-quadrant mass seemed to decrease in size, as did a fullness in the right vault on the eighth day, when foul, liquid bowel movements began. Active normal peristalsis was heard at this time, and for five days she tolerated liquids by mouth with the Miller-Abbott tube out. On the sixteenth day she began to vomit fresh blood and coffee-ground material and to pass fresh clots by rectum. The blood pressure fell to 80 systolic, 60 diastolic, and the patient complained of anginal pain.

Transfusion of 1000 cc of whole blood produced some clinical improvement, but on the morning of the eighteenth day she suddenly became disoriented, the heart beat and respirations ceased, and she was pronounced dead.

DIFFERENTIAL DIAGNOSIS

DR REED HARWOOD: May we see the x-ray films?

DR JAMES A. McCORT: The x-ray examination was limited to a plain film of the abdomen. The tip of a Miller-Abbott tube is present in the fundus of the stomach. Distal to the stomach there are at least two dilated loops of small bowel. Air is present in the ascending colon. There may also be a small amount of air in the descending colon and sigmoid. The mass described in the protocol is not visible on the x-ray film.

DR HARWOOD: Is that a pressure defect?

DR McCORT: There is not a sufficient amount of air in the cecum for me to be certain.

DR HARWOOD: The history, then, is one of intestinal obstruction that relieved itself after eight days in the hospital. Ten days later the patient vomited fresh blood and also passed fresh blood by rectum and rapidly went into shock and died.

I am first going to present a list of conditions that I think we should consider, with a comment on each: metastatic carcinoma or recurrence of one of the previous carcinomas, a new carcinoma

of the colon or a tumor of the ileum, with intussusception, and tuberculosis of the cecum, diverticulitis and mesenteric thrombosis.

Regarding metastatic carcinoma, the patient had two previous operations for carcinoma in the past. The first one was twenty years before admission, when her breast was removed, and the other was for carcinoma of the uterine fundus twelve years previously. It seems to me that the objection to postulating recurrence of metastasis from either of these two primary tumors is the duration since the tumor was removed. We know that occasionally there is a late recurrence of carcinoma. In both cases, I would expect a recurrence to appear either in the lungs, the liver or the bone marrow. Therefore, I am excluding metastatic carcinoma.

We know from previous exercises that it is not at all uncommon for a patient to have two or three carcinomas in different organs of the body. Perhaps this patient had a predisposition for the formation of malignant tumors. The history is good for carcinoma of the bowel. She had chronic constipation and a down-hill course for over a period of two years, with increasing constipation, finally ending in obstruction. The physical findings are consistent with such a diagnosis. We know with carcinoma of the right colon that the typical history is alternating periods of constipation and diarrhea, but there is no suggestion that she had diarrhea in the past two years. The obstruction was relieved in this case, and I should not expect that to occur in carcinoma that has slowly encircled the lumen of the cecum or ascending colon. Tumor of the ileum with intussusception and intussusception from a tumor in the region of the cecum are both possibilities that are attractive because of the fact that after eight days in the hospital the obstruction was relieved and she passed foul, liquid bowel movements. I would rather expect this patient to have been much sicker, possibly in shock, with a much higher white-cell count if she had had intussusception on admission.

Tuberculosis of the cecum can cause both bleeding and obstruction. I think it is unlikely in this case because of the absence of any suggestion of tuberculosis in the lung.

Diverticulitis, possibly with abscess formation and discharge of the contents of the abscess into the lumen of the bowel, might possibly explain the relief of obstruction in this case. Diverticulitis is much more common in the left colon than in the right. I merely mention this as a possibility, I cannot prove it.

Finally, we come to a consideration of mesenteric thrombosis, venous or arterial. If arterial, it could have been the result of arteriosclerosis of the mesenteric arteries or an embolus from some other source. We know, for example, that the patient had arteriosclerotic heart disease, and it is possible, although I think unlikely, that she had had a coronary occlusion in the recent past and an embolus from a

type of study that Gordon has so successfully developed

PEDIATRIC SURVEY

THE nationwide study of health services for children conducted by the American Academy of Pediatrics during the past three years, state by state, has been published by the Commonwealth Fund and reviewed in the *Journal* of September 8. In the current issue can be found a brief but explicit summary of the report on the Massachusetts survey.

Wholly aside from the statewide study, Massachusetts appears to have figured prominently in the national picture. Dr Warren R Sisson, of Boston, was chairman of the Committee for the Study of Child Health Services when the pilot study in North Carolina was undertaken in 1945, and is currently president of the Academy as the reports are being issued. Dr John P Hubbard, also *loc cit*, has been executive director of the entire survey from its inception.

The study has been decentralized to an unusual degree, each state chairman having been required to develop his own organization, plan the financing of the work and arrange for the publication of the findings. The report on the Massachusetts Survey is published by the American Academy of Arts and Sciences.

In general, throughout the state surveys, data have been tabulated by counties and by the metropolitan character of counties, a classification that depends on both population density and proximity to centers of population. Only three of the fourteen counties of Massachusetts — Barnstable, Dukes and Nantucket, are classed as "isolated," and it has been found practical in this state to utilize the public-health districts in preference to county divisions.

Certain not altogether palatable data have been brought out by the survey. Massachusetts is the twelfth wealthiest state in the Union but ranks twenty-second in maternal and twentieth in infant

mortality. Boston in particular has an infant-mortality rate one point higher than the national average, despite the fact that the Commonwealth ranks third among the states with respect to the total amount of medical service that its children receive, and second with respect to the number of practicing physicians in relation to population. It ranks fifth with respect to the number of dentists in practice.

The training of physicians and dentists in the specialized care of children has been found on the whole to be deficient, the average general practitioner requiring more pediatric training both in medical school and in the hospital than he is now receiving.

The distribution and utilization of pediatric hospital beds is uneven, a prime need in the field of chronic care being for more beds for mentally deficient and epileptic patients. A program for graduate pediatric education is desirable, this could be sponsored by the Massachusetts Medical Society, the New England Pediatric Society and the Massachusetts Chapter of the American Academy of Pediatrics.

Criticism in any field of endeavor is of value in direct relation to the available knowledge on which it is based. The work that Baty and Snedeker have done in Massachusetts in straight fact-finding, which can be multiplied by the number of states in the union, is impressive. It is now the responsibility of the medical profession and of the public to convert this information into an active program.

The channels through which medical service flows and the methods by which it becomes available may change from generation to generation and may be often the subject of debate. The obligation of the profession to provide the best service possible to all who need it never changes.

PUBLIC HEALTH AND PRIVATE PRACTICE

DR HENRY I BOWDITCH, of Boston, — then chairman of the Massachusetts State Board of Health, — enunciated the following principle in the Centennial Discourse on Public Hygiene delivered at the Philadelphia Exposition in 1876:

Still further I hold it to be true that the study of the prevention of disease is the only branch of medical learning

EPIDEMIOLOGY OF TRAUMA

ONLY a study of all the factors that affect health can lead to an intelligent program for its preservation. In the field of trauma, as Gordon¹ has previously pointed out, any organized approach to the problem of accidents, occurring singly or in catastrophic numbers, was originally centered on relief. It was for relief that the Red Cross was organized—first for the relief of stricken soldiers, then, under the American Amendment, for the relief of civilians in time of disaster. Not until later did the idea of prevention begin to prevail, and then it was advanced mainly by industry.

Elsewhere the same author² has indicated the growth of the concept of the epidemiologic method from its original restriction to the communicable diseases to a broader application to the other afflictions of mankind as well as including such conditions as cancer and diabetes and even the con-

genital malformations. Epidemiology, as a study of cause and effect in their relation to health, can be equally well applied to an investigation of the traumatic hazards.

These possibilities can be variously illustrated by analyses of "point" epidemics, representing "that circumstance where a sharp aggregation of cases occurs within a brief interval as the result of a single agent acting during a prescribed and limited time." In this category is the explosive eruption of typhoid-fever cases two weeks after a circus train inadvertently filled its tanks from a standpipe delivering untreated river water. The accidental deaths occurring as a result of the Coconut Grove fire in Boston in 1942 were in the same class, as was the outbreak of trench foot in an infantry division following the Battle of the Bulge.

Three factors, or some combination of the three, are involved when the "established and satisfactory equilibrium or adjustment between man and his environment" that is called health is disturbed. These are the direct causative factor or agent, the environmental factor, and the host factor.

A study of them all is important if a practical program of control is to be worked out. Not only can the epidemiology of accidents be analyzed in the same manner as that of disease, but practical preventive measures will result from a survey of the causative factors.

In this issue of the *Journal* Roberts and Gordon present an investigation into the epidemiology of home accidents as they occur in Massachusetts. The Massachusetts accident death rate is lower than that for the country as a whole, but the Commonwealth's low automobile death rate is responsible. Fatal home accidents are actually proportionately more important in Massachusetts than in the nation.

Not only do the authors present a statistical analysis of the local status, but advice regarding the studies on which efficient control methods can be based.

In respect to the epidemiology of trauma it is interesting to note that considerable attention is now being focused on accidents occurring on the farm. Here, where a high rate of unnecessary mishaps is being reported, is a fruitful field for the

OBITUARY

FREDERIC AUGUSTUS WASHBURN

1869-1949

Dr Frederic Augustus Washburn, former director of the Massachusetts General Hospital, died on August 20, 1949. He had served as director of the hospital from 1908 until his retirement in 1934.

Dr Washburn was born in New Bedford in 1869. He graduated from Amherst College in 1892 and received his medical degree from Harvard Medical School four years later. His service at the Massachusetts General Hospital began in 1897, when he was appointed house officer on the South Surgical Service. He became director of the Massachusetts Eye and Ear Infirmary in 1915.

He was surgeon and first lieutenant with the Sixth Massachusetts Volunteers in the Porto Rico Campaign (1898-99), assistant surgeon and captain with the Twenty-Sixth U S Volunteers in the Philippines (1899-1903) and major and colonel in World War I, during which he organized and commanded Base Hospital No 6, later he was in charge of all United States Army hospitals in Great Britain, receiving the Distinguished Service Medal and the orders of St Michael and St George.

In 1930 Dr Washburn founded the Baker Memorial Hospital for the care of people of moderate means, with hospital charges at cost and a limited professional fee. After his retirement he was appointed Commissioner of Institutions for the city of Boston. From 1937 to 1946 he was director of the Cambridge Hospital (now the Mount Auburn Hospital).

He was a former president of the American Hospital Association and was a fellow of the American Medical Association.

Dr Washburn was noted for his ability as an administrator as well as for the charm of his personality. He will be greatly missed by all those with whom he was associated, both in his professional capacity and as a friend.

N W F

NEW HAMPSHIRE MEDICAL SOCIETY

DEATHS

BAKER—Benjamin W Baker, M D, of Laconia, died on August 17. He was in his seventy-sixth year.

Dr Baker received his degree from Dartmouth Medical School in 1898. He was formerly medical director and superintendent of the Laconia State School and was a member of the New England Society of Psychiatry and the American Psychiatric Association and a fellow of the American Medical Association.

His widow, a daughter and a brother survive.

WEAVER—George A Weaver, M D, of Bradford, Vermont, died on June 22. He was in his eighty-first year.

Dr Weaver received his degree from Yale University School of Medicine in 1897. He was a fellow of the American Medical Association, and on June 15, 1949, had received a medal commemorating his fifty years' membership in the New Hampshire Medical Society.

His widow, a son, a daughter, two grandchildren and a sister survive.

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

CONSULTATION CLINICS FOR CRIPPLED CHILDREN IN MASSACHUSETTS

The October schedule for Consultation Clinics for Crippled Children in Massachusetts under the provisions of the Social Security Act follows:

CLINIC	DATE	CLINIC CONSULTANT
Salem	October 3	Paul W. Hugenberger
Haverhill	October 5	William T. Green
Lowell	October 7	Albert H. Brewster
Greenfield	October 10	Charles L. Sturdevant
Gardner	October 11	Carter R. Rowe
Brockton	October 13	George W. Van Gorder
Springfield	October 18	Garry deN. Hough, Jr
Pittsfield	October 19	Frank A. Slowick
Worcester	October 21	John W. O'Meara
Fall River	October 24	David S. Grice
Hyannis	October 27	Paul L. Norton

Physicians referring new patients to clinics should get in touch with the district health officer to make appointments. Patients are seen by appointment only.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Reproduction and Survival. By R. Christie Brown, M B, M S, F R C S, F R C O G, obstetric surgeon, City of London Maternity Hospital, honorary surgeon, Samaritan Free Hospital for Women, and gynecologist, Metropolitan Hospital 12, cloth, 108 pp. London: Edward Arnold and Company, 1948. \$2.25.

Psychiatry, A short treatise. By William A. O'Connor, L M S S A (Lond.), D P M (Lond.), medical superintendent, Ashwood House, Kinswinford, Staffs., and tutor (psychology) of extra-mural, University, and W E A classes 8, cloth, 380 pp. Baltimore: Williams and Wilkins Company, 1948. \$9.00.

Conditioned Reflexes and Neuron Organization. By Jerzy Konorski, head of the Department of Neurophysiology in the Nencki Institute of Experimental Biology, and professor in the University of Lodz. Translated from the Polish manuscript under the author's supervision by Stephen Garry 8, cloth, 267 pp., with 18 illustrations. Cambridge: University Press, New York: Macmillan Company, 1948. \$4.00 (Cambridge Biological Studies).

which the State can legitimately undertake. The practice of medicine and surgery and the appropriate use of drugs, must be left to medical schools and to private practitioners of medicine. The State, as a student of the causes of all disease, only supplements, and indeed nobly supplements them.*

In those days, too, there were giants in the earth.

Aside from the present aims and future goals of state and federal Government in relation to health and disease, it is obvious that considerably more oversight of health in general is being exercised in 1949 than was the case in 1876. Nor is all of this paternalistic solicitude to be condemned. Public health and private practice when each is properly conducted have but one common goal and, when each is conducted properly, that goal can be approached with mutual harmony and consideration.

Even Dr. Bowditch, amazed as he might be at group health insurance and shocked as he certainly would be at the current efforts of Government to introduce compulsory health insurance, would nevertheless have considered it a proper function of the State to care for its military personnel, its veterans (to a degree) and its indigent. He, too, would have believed it to be a function of public health to co-operate with the private practitioner, and would have expected the practitioner on his part to co-ordinate his efforts with those of public health, and to reap its benefits. Certainly the physician who today opposes this policy must accept the burden of proving that he is right in doing so.

It is this capacity of public and private service for working together that has been ably demonstrated in the public-health heart program instituted a year ago in Newton, Massachusetts, and reported elsewhere in this issue of the *Journal*.

This program, conceived as a pilot study of the public-health aspects of heart disease was endorsed by the Massachusetts Medical Society in May, 1948, and activated under the joint sponsorship of the Newton Health Department, the Massachusetts Department of Public Health and the United States Public Health Service. Its objectives are "to determine methods of helping to reduce cardiovascular disease and conserve cardiac

function", its program is based on the belief that heart disease constitutes a public-health problem, and that public-health measures will yield results in its control. It early received the endorsement of the Newton Medical Club and has progressed to the point of its present report through the co-operation of the practicing profession.

MEDICAL ILLUSTRATION

AN ESSENTIAL part of medical publication is adequate illustration. The point of an article is often made quite as much by an expert drawing of a part of the body or a carefully worked out diagram as by a description in words, indeed, a clear, professionally presented illustration is occasionally of more value than paragraphs of text.

Those who write for publication in medical journals will therefore be interested in the fourth annual convention of the Association of Medical Illustrators, which will be held in Boston from October 3 through October 6. Founded in 1946, the Association is dedicated to the following purpose: "to advance medical education and to promote understanding and co-operation with the medical and related professions."

The program of the convention includes talks by members of the Association on the administration of their departments, with discussions led by Dr. Joseph S. Lichty, an exhibition of work by members, an address by Dr. Robert M. Green and meetings in the Ether Dome of the Massachusetts General Hospital, with a demonstration of air-brush technique, a description of a new "Colotone" printing process and a lecture on the use of plastic materials. Of particular interest is the memorial lecture, delivered by Dr. Reginald Fitz, which commemorates the work of Max Brodell, who for thirty years conducted the Department of Art as Applied to Medicine at Johns Hopkins University School of Medicine and under whom many members of the Association studied.

It is hoped that the convention of specialists in what may be considered an adjunct to medical science will be as successful and informative as the meetings held in previous years in Philadelphia, New Orleans and Chicago.

COMBINED MEDICAL AND SURGICAL MANAGEMENT OF UPPER GASTROINTESTINAL HEMORRHAGE*

THOMAS A. WARTHIN, M.D.,† RICHARD WARREN, M.D.,‡ AND EGON G. WISSING, M.D.§

WEST ROXBURY, MASSACHUSETTS

MANY excellent reviews of the problems in management of upper gastrointestinal bleeding have been presented by various internists and surgeons. Almost without exception the material has been analyzed from the point of view of the internist or the surgeon. Rarely has the combined approach been presented, although recent papers by Jones,¹ Heuer,² Schatzki³ and Hoerr⁴ have emphasized this. It is our purpose to demonstrate that the most efficient way to deal with massive bleeding is by means of a combined medical and surgical team in conjunction with a well trained roentgenologist. In the Veterans Administration Hospital, West Roxbury, such a team has been in existence during the past two and a half years.

MATERIAL

Although a combined medical and surgical responsibility in the therapy of upper gastrointestinal bleeding is most applicable when the source of hemorrhage is a peptic ulcer, the matter of diagnosis is so implicated with that of treatment that such a team must inevitably consider in some degree all causes of the hemorrhage. During the period from July 1, 1946, to June 30, 1948, 10,342 patients were admitted to the hospital, of whom 181 had upper gastrointestinal bleeding as their primary complaint. It has been convenient to divide these patients into three groups — massive, intermediate and slight — according to the severity of the hemorrhage. The massive group was composed of 86 patients and included those in whom the red-cell count fell below 3,000,000. The intermediate group, in which hemorrhage was sufficient to effect a fall in the red-cell count to less than 4,000,000 but

greater than 3,000,000, contained 50 patients. In addition, 45 cases of slight hemorrhage occurred in which the red-cell count did not fall below 4,000,000. Of total hospital admissions 1.7 per cent were for upper gastrointestinal bleeding, 0.8 per cent being for massive hemorrhage. During the same period 494 patients with simple or complicated peptic ulcer were admitted to the hospital, 117, or 23 per cent, for hemorrhage. Of the 86 cases of massive hemorrhage 56, or 65 per cent, were demonstrated to be due to peptic ulceration, whereas the remaining 30 were due to esophageal varices, gastritis or undetermined conditions. Table 1 illustrates the dispersion of the cases according to source of the hemorrhage, the various diagnoses listed in the cases without ulcer are similar to those observed in other clinics (Hoerr⁴ and Stolte⁵). It is of interest that in 15 per cent of the patients no site of origin of the hemorrhage could be demonstrated, and that in only 3 of these 14 patients could a history suggestive of ulcer be obtained. Reports from other clinics also contain a seemingly irreducible number of patients who must be put in this undiagnosed group. The origin of their hemorrhages will probably always remain obscure.

In 65 per cent of patients admitted for massive upper gastrointestinal bleeding the source was demonstrated to be a peptic ulceration. Among this group 85.7 per cent of cases were due to duodenal ulcer, 12.6 per cent to gastric ulcer, and 1.7 per cent to marginal ulcer. The ratio of these three types of ulcers to each other is comparable with that found in any group of ulcers whether bleeding or not. In the intermediate and slight groups a similar ratio of bleeding due to ulcer and other conditions was obtained.

MORTALITY

Eleven of our 86 patients with massive upper gastrointestinal hemorrhage died — a mortality of 12.8 per cent. Only 2 of these were in the ulcer group of 56 patients (a mortality of 3.6 per cent for massively bleeding peptic ulcer). Nine of 30 patients with massive bleeding from conditions

NOTICES

BOSTON CITY HOSPITAL HOUSE OFFICERS' ASSOCIATION

The first in a series of Tuesday evening lectures for the 1949-1950 season sponsored by the Boston City Hospital House Officers' Association will be held in the Dowling Amphitheater, Boston City Hospital, on Tuesday, October 4, at 7 p.m. Dr. Harold Jeghers, professor of medicine, Georgetown University School of Medicine, will speak on the subject "Fever of Undetermined Etiology."

All interested persons are invited to attend.

ASSOCIATION OF MEDICAL ILLUSTRATORS

The annual meeting of the Association of Medical Illustrators will be held in Boston October 3 through 6. Dr. Reginald Fitz will deliver the opening address at the Lincolnshire Hotel on the first day of the meeting. The subsequent sessions will consist of committee reports, discussions, led by Dr. Joseph S. Lichty, of the administration of departments, demonstrations of color presswork, air-brush technique and a description of a new "Colotone" printing process, and a lecture on the use of plastic materials. A medical motion picture, a tour of the Massachusetts General Hospital and the annual dinner will also be included among the activities of the convention.

AIR FORCE MEDICAL SERVICE

The United States Air Force Medical Service will commission 300 civilian physicians, now serving as interns, as first lieutenants on active duty with the Air Force Medical Reserve Corps.

Eligible to receive commissions are medical-school graduates now serving internships at approved hospitals, who

have at least six months of internship remaining. Physicians who are so commissioned will serve two months of active duty for each month of internship as commissioned members of the Medical Reserve Corps.

Upon completion of active-duty tours, officers who apply and are selected as members of the regular Air Force Medical Corps will be eligible for participation in the Air Force residency program to be conducted at civilian and military hospitals.

Officers who do not apply for commissions in the regular Air Force, and who do not participate in the residency program, may continue to serve on active duty as reserve officers for specific periods.

Complete information concerning the intern program may be obtained upon written request to the Officer's Procurement Branch, Office of the Surgeon General, Headquarters, United States Air Force, Washington, 25, D. C.

COMBINED MEDICAL AND SURGICAL MANAGEMENT OF UPPER GASTROINTESTINAL HEMORRHAGE*

THOMAS A. WARTHIN, M.D.,† RICHARD WARREN, M.D.,‡ AND EGON G. WISSING, M.D.§

WEST ROXBURY, MASSACHUSETTS

MANY excellent reviews of the problems in management of upper gastrointestinal bleeding have been presented by various internists and surgeons. Almost without exception the material has been analyzed from the point of view of the internist or the surgeon. Rarely has the combined approach been presented, although recent papers by Jones,¹ Heuer,² Schatzki³ and Hoerr⁴ have emphasized this. It is our purpose to demonstrate that the most efficient way to deal with massive bleeding is by means of a combined medical and surgical team in conjunction with a well trained roentgenologist. In the Veterans Administration Hospital, West Roxbury, such a team has been in existence during the past two and a half years.

MATERIAL

Although a combined medical and surgical responsibility in the therapy of upper gastrointestinal bleeding is most applicable when the source of hemorrhage is a peptic ulcer, the matter of diagnosis is so implicated with that of treatment that such a team must inevitably consider in some degree all causes of the hemorrhage. During the period from July 1, 1946, to June 30, 1948, 10,342 patients were admitted to the hospital, of whom 181 had upper gastrointestinal bleeding as their primary complaint. It has been convenient to divide these patients into three groups — massive, intermediate and slight — according to the severity of the hemorrhage. The massive group was composed of 86 patients and included those in whom the red-cell count fell below 3,000,000. The intermediate group, in which hemorrhage was sufficient to effect a fall in the red-cell count to less than 4,000,000 but

greater than 3,000,000, contained 50 patients. In addition, 45 cases of slight hemorrhage occurred in which the red-cell count did not fall below 4,000,000. Of total hospital admissions 1.7 per cent were for upper gastrointestinal bleeding, 0.8 per cent being for massive hemorrhage. During the same period 494 patients with simple or complicated peptic ulcer were admitted to the hospital, 117, or 23 per cent, for hemorrhage. Of the 86 cases of massive hemorrhage 56, or 65 per cent, were demonstrated to be due to peptic ulceration, whereas the remaining 30 were due to esophageal varices, gastritis or undetermined conditions. Table 1 illustrates the dispersion of the cases according to source of the hemorrhage, the various diagnoses listed in the cases without ulcer are similar to those observed in other clinics (Hoerr⁴ and Stolte⁵). It is of interest that in 15 per cent of the patients no site of origin of the hemorrhage could be demonstrated, and that in only 3 of these 14 patients could a history suggestive of ulcer be obtained. Reports from other clinics also contain a seemingly irreducible number of patients who must be put in this undiagnosed group. The origin of their hemorrhages will probably always remain obscure.

In 65 per cent of patients admitted for massive upper gastrointestinal bleeding the source was demonstrated to be a peptic ulceration. Among this group 85.7 per cent of cases were due to duodenal ulcer, 12.6 per cent to gastric ulcer, and 1.7 per cent to marginal ulcer. The ratio of these three types of ulcers to each other is comparable with that found in any group of ulcers whether bleeding or not. In the intermediate and slight groups a similar ratio of bleeding due to ulcer and other conditions was obtained.

MORTALITY

Eleven of our 86 patients with massive upper gastrointestinal hemorrhage died — a mortality of 12.8 per cent. Only 2 of these were in the ulcer group of 56 patients (a mortality of 3.6 per cent for massively bleeding peptic ulcer). Nine of 30 patients with massive bleeding from conditions

NOTICES

BOSTON CITY HOSPITAL HOUSE OFFICERS' ASSOCIATION

The first in a series of Tuesday evening lectures for the 1949-1950 season sponsored by the Boston City Hospital House Officers' Association will be held in the Dowling Amphitheater, Boston City Hospital, on Tuesday, October 4, at 7 p.m. Dr. Harold Jeghers, professor of medicine, Georgetown University School of Medicine, will speak on the subject "Fever of Undetermined Etiology."

All interested persons are invited to attend.

ASSOCIATION OF MEDICAL ILLUSTRATORS

The annual meeting of the Association of Medical Illustrators will be held in Boston October 3 through 6. Dr. Reginald Fitz will deliver the opening address at the Lincolnshire Hotel on the first day of the meeting. The subsequent sessions will consist of committee reports, discussions, led by Dr. Joseph S. Lichty, of the administration of departments, demonstrations of color presswork, air-brush technique and a description of a new "Colotone" printing process, and a lecture on the use of plastic materials. A medical motion picture, a tour of the Massachusetts General Hospital and the annual dinner will also be included among the activities of the convention.

AIR FORCE MEDICAL SERVICE

The United States Air Force Medical Service will commission 300 civilian physicians, now serving as interns, as first lieutenants on active duty with the Air Force Medical Reserve Corps.

Eligible to receive commissions are medical-school graduates now serving internships at approved hospitals, who

have at least six months of internship remaining. Physicians who are so commissioned will serve two months of active duty for each month of internship as commissioned member of the Medical Reserve Corps.

Upon completion of active-duty tours, officers who apply and are selected as members of the regular Air Force Medical Corps will be eligible for participation in the Air Force residency program to be conducted at civilian and military hospitals.

Officers who do not apply for commissions in the regular Air Force, and who do not participate in the residency program, may continue to serve on active duty as reserve officers for specific periods.

Complete information concerning the intern program may be obtained upon written request to the Officer's Procurement Branch, Office of the Surgeon General, Headquarters, United States Air Force, Washington, 25, D.C.

and response to conservative therapy that might prove of assistance in arriving at a correct diagnosis. The average ages in the ulcer and nonulcer group did not differ significantly, being forty-one and forty-four years respectively. Although the duration of bleeding prior to admission tended to be shorter and other evidences of severity of hemorrhage (fainting, sudden onset, hematemesis) tended to be more pronounced in the patients bleeding from esophageal varices than in the other groups, little statistical difference could be found between the ulcer and nonulcer groups if they were taken as a whole. Hematemesis was absent in a considerable number of each group but not enough in any one to help in distinguishing the various diagnoses in question. It was present in all the patients who died or were operated on and in 65 per cent of the patients with duodenal ulcer and massive hemorrhage. It occurred in only 40 per cent of the less severely bleeding ("intermediate") group. We must agree with Meulengracht⁶ that in general the absence of hematemesis means, even if the ulcer is beyond the pylorus, a less serious degree of bleeding than if it is present.

Although in the ulcer groups some factors that caused emotional or physical strain or overtaxed the gastrointestinal tract were present in over half the patients before they bled from ulcer, the same conditions were observed in almost half the patients bleeding from other causes. The most common of these factors was overindulgence in food or alcoholic beverages or the assumption of unusual responsibility such as is attendant on a business reverse or crisis, an impending marriage or the moving of a household. Infections and the use of salicylates occurred as possible precipitants in both groups. In 60 per cent of the patients with ulcer there was a premonitory symptom of ulcer activity—that is, pain or vomiting. In the nonulcer group false signs of ulcer activity were present in only 4 cases, 2 of which were in the group in which no cause could be found; clinically, these patients were ulcer suspects even though x-ray films failed to show an ulcer crater. This finding is of importance in differential diagnosis and also has obvious prophylactic implications in that it behooves patients with ulcer to heed such symptoms early and to seek treatment promptly.

Sixty-eight per cent of all patients with ulcer who bled suffered ulcer pain during hemorrhage. Among the patients without ulcers there were 3 who had false ulcer pain. Two of these were ulcer suspects but had normal gastrointestinal x-ray films. The other patient also had bleeding of undetermined cause. This symptom, therefore, if present, is a helpful one in making the differential diagnosis between hemorrhage from peptic ulcer and that from other causes. Forty-seven of the 56 patients (84 per cent) with bleeding from peptic ulcer gave a history of previous symptoms of postprandial distress that could be interpreted as being

due to ulcer. False symptoms, sufficient to have suggested a clinical diagnosis of ulcer were present, however, in 11 of the 30 nonulcer bleeders (36.6 per cent), 10 of whom had gastritis or hemorrhage of undetermined cause. This degree of incidence among the nonulcer group suggests that a history of previous symptoms is unreliable in aiding differential diagnosis.

Among the patients with ulcer 35 had had a definite, previous diagnosis of ulcer, confirmed by x-ray study, among the patients without ulcers there were but 2 in whom the diagnosis had been made. A definite previous diagnosis of ulcer, if present, is therefore significant.

The incidence of previous hemorrhage in the patients studied was not significant. No conclusions can be drawn since slightly more than two thirds of our patients were admitted during their first hemorrhage and slightly less than a third during subsequent hemorrhages. Since gastritis is a condition generally associated with multiple hemorrhages, we were surprised to find that only 1 of these patients had bled previously before admission to the hospital.

The drinking habits of the 65 patients of the total of 86 in the series in whom an adequate history in this regard was obtainable are interesting. It is striking that 34, or more than half, of the patients were heavy drinkers, and that this applied to 17 of 21, or 81 per cent, of the nonulcer group, and to 17 of 44, or 38.6 per cent, of the ulcer bleeders. It is of interest that only 1 patient of 21 in the nonulcer group was an abstainer. None of these distinctions, however, were clear-cut enough to help us definitely with differential diagnosis in the individual case.

Physical Examination

The physical examination included inspection for the so-called ulcer facies, a careful search for stigmas of cirrhosis—namely, a large, percussible or palpable liver or spleen and jaundice—and inspection of the face, shoulders, arms and back for spider telangiectasias. It was discovered that during the height of hemorrhage and shock enlarged spleens were often too soft to be felt, and spider telangiectasias too faint to be visible. The degree of arteriosclerosis was always estimated.

Hemoglobin, red-cell counts and hematocrit determinations were made daily as long as signs of hemorrhage persisted and at less frequent intervals thereafter. As soon as possible, determinations were made to rule out the presence of a hepatic or metabolic disturbance.

Emergency X-ray Study

The early roentgenologic examination in patients bleeding from the gastrointestinal tract was initiated by Hampton⁷ and has been discussed by Schatzki,⁸ who gives a thorough description of the technic. Here we shall only mention in brief that a thin

other than ulcer died, however—a mortality of 30 per cent. Table 2 reveals the causes of death in the 11 cases of massive bleeding. Two facts of interest stand out here. The first is that in only 6 of the 11 cases was hemorrhage the primary cause of death. In the other 5 the patients died of other

operation, of lobar pneumonia. Here arteriosclerosis played no part, but portal hypertension, which had developed after a traumatic portal-vein thrombosis, and pneumonia made the bleeding ultimately fatal. The second death from ulcer was in a sixty-seven-year-old man with a gastric ulcer, advanced

*The primary cause of death was hypertensive cardiovascular disease.

†These diagnoses were carcinoma of the stomach, cirrhosis without demonstrable varices, and leiomyoma of the stomach.

causes—liver failure in 3, peritonitis and malnutrition in 1, and terminal carcinoma of the stomach in 1. Secondly, 10 of the 11 patients who died had either hepatic cirrhosis or portal hypertension as a primary or secondary diagnosis. In the 3 of these 10 that were not bleeding frankly from esophageal varices the sources of bleeding were gastric ulcers in 2 and undetermined in 1. From these facts it appears that one must agree with the conclusion of Meulengracht⁶ that the dangerous bleeders are those whose bleeding is due to or complicated by factors that interfere with nutrition or the normal state of the gastrointestinal blood vessels. Arteriosclerosis is undoubtedly the most common unfavorable complicating factor that renders the hemorrhage

operation and carcinoma of the liver, death occurring within thirty-six hours of admission to the hospital.

MANAGEMENT

All patients with gastrointestinal hemorrhage were admitted to the Medical Service, but within twenty-four hours of arrival and as soon as the diagnosis of massive hemorrhage had been made the patient was seen by the surgical member of the team, who then followed the case with frequent consultations with the internist.

Diagnosis

Since the accurate diagnosis of the source of the bleeding was an important determination in

TABLE 2 Causes of Death in Patients with Upper Gastrointestinal Hemorrhage

PATIENT	AGE	SOURCE OF HEMORRHAGE	AUTOPSY	DEGREE OF HEMORRHAGE	CHIEF CAUSE OF DEATH	OTHER DIAGNOSES
H. W. L.	26	Gastric ulcer	Yes	Massive	Hemorrhage	Portal hypertension, pneumonia

W. A. B.	51	Gastric mucosa	Yes	Massive	Cirrhosis of liver	Hemorrhage

dangerous. We believe, however, that it is not the only one. Others, such as portal hypertension and hepatic cirrhosis, were important in our series. One of the 2 deaths from massive bleeding in peptic ulcer occurred in a twenty-six-year-old man with a gastric ulcer who died, two days after an emergency

any surgical therapy was to be undertaken, special attention was paid to the diagnosis as obtained by the usual methods and to the reliability thereof. In addition, a study was made in the cases of massive hemorrhage of certain special considerations, such as previous diagnoses, habits, type of bleeding

and response to conservative therapy that might prove of assistance in arriving at a correct diagnosis. The average ages in the ulcer and nonulcer group did not differ significantly, being forty-one and forty-four years respectively. Although the duration of bleeding prior to admission tended to be shorter and other evidences of severity of hemorrhage (fainting, sudden onset, hematemesis) tended to be more pronounced in the patients bleeding from esophageal varices than in the other groups, little statistical difference could be found between the ulcer and nonulcer groups if they were taken as a whole. Hematemesis was absent in a considerable number of each group but not enough in any one to help in distinguishing the various diagnoses in question. It was present in all the patients who died or were operated on and in 65 per cent of the patients with duodenal ulcer and massive hemorrhage. It occurred in only 40 per cent of the less severely bleeding ("intermediate") group. We must agree with Meulengracht⁶ that in general the absence of hematemesis means, even if the ulcer is beyond the pylorus, a less serious degree of bleeding than if it is present.

Although in the ulcer groups some factors that caused emotional or physical strain or overtaxed the gastrointestinal tract were present in over half the patients before they bled from ulcer, the same conditions were observed in almost half the patients bleeding from other causes. The most common of these factors was overindulgence in food or alcoholic beverages or the assumption of unusual responsibility such as is attendant on a business reverse or crisis, an impending marriage or the moving of a household. Infections and the use of salicylates occurred as possible precipitants in both groups. In 60 per cent of the patients with ulcer there was a premonitory symptom of ulcer activity—that is, pain or vomiting. In the nonulcer group false signs of ulcer activity were present in only 4 cases, 2 of which were in the group in which no cause could be found; clinically, these patients were ulcer suspects even though x-ray films failed to show an ulcer crater. This finding is of importance in differential diagnosis and also has obvious prophylactic implications in that it behooves patients with ulcer to heed such symptoms early and to seek treatment promptly.

Sixty-eight per cent of all patients with ulcer who bled suffered ulcer pain during hemorrhage. Among the patients without ulcers there were 3 who had false ulcer pain. Two of these were ulcer suspects but had normal gastrointestinal x-ray films. The other patient also had bleeding of undetermined cause. This symptom, therefore, if present, is a helpful one in making the differential diagnosis between hemorrhage from peptic ulcer and that from other causes. Forty-seven of the 56 patients (84 per cent) with bleeding from peptic ulcer gave a history of previous symptoms of postprandial distress which could be interpreted as being

due to ulcer. It is striking that 34, or more than half, of the patients were heavy drinkers, and that this applied to 17 of 21, or 81 per cent, of the nonulcer group, and to 17 of 44, or 38.6 per cent, of the ulcer bleeders. It is of interest that only 1 patient of 21 in the nonulcer group was an abstainer. None of these distinctions, however, were clear-cut enough to help us definitely with differential diagnosis in the individual case.

Physical Examination

The physical examination included inspection for the so-called ulcer facies, a careful search for stigmas of cirrhosis—namely, a large, percussible or palpable liver or spleen and jaundice—and inspection of the face, shoulders, arms and back for spider telangiectasias. It was discovered that during the height of hemorrhage and shock, enlarged spleens were often too soft to be felt, and spider telangiectasias too faint to be visible. The degree of arteriosclerosis was always estimated.

Hemoglobin, red-cell counts and hematocrit determinations were made daily as long as signs of hemorrhage persisted and at less frequent intervals thereafter. As soon as possible, determinations were made to rule out the presence of a hepatic or metabolic disturbance.

Emergency X-ray Study

The early roentgenologic examination in patients bleeding from the gastrointestinal tract was initiated by Hampton⁷ and has been discussed by Schatzki,⁸ who gives a thorough description of the technic. Here we shall only mention in brief that a thin

barium suspension was used, that the patient was examined in the prone and supine positions only, and that compression technic was not employed. Our indications for such emergency x-ray examination were as follows: persistent or recurrent bleeding in a patient on whom we were prepared to perform urgent surgery if the diagnosis of ulcer was definitely established, recurrent bleeding in a patient in whom previous studies had failed to determine the source of the hemorrhage. In each case the surgical member of the team agreed to the need of emergency x-ray examination, an adequate stock of matched blood for transfusions was on hand,

but six hours later on the ward, and was not fatal. Another patient, a man of fifty-six, entered the hospital with a massive hemorrhage and gave a history of having had a duodenal ulcer for years. To corroborate this he gave a history of having had a perforation sutured six months before and demonstrated an abdominal scar to prove it. Since he was in the older age group and did not respond to medical therapy within forty-eight hours, operation was strongly considered and planned. An emergency barium meal was thought by many to be superfluous in this case. It was performed, however, and large esophageal varices were seen,

TABLE 3 *Results of Operation*

and a room was available in the operating suite for the immediate transfer of the patient should further hemorrhage occur or a lesion be found that would indicate that early operation was necessary. All emergency x-ray examinations were rechecked six to twelve days after bleeding had ceased. Of our 86 patients 19, or 22 per cent, had an emergency gastrointestinal series performed during bleeding. In 17 of these patients a satisfactory examination was obtained and a diagnosis made either by positive findings or by exclusion, no additional information being obtained by subsequent elective x-ray study. In 1 patient the examination was unsatisfactory and was recognized as such, so that therapy was not thereby influenced. In another, the first case of the series (J L S, Table 3), a possible diagnosis of duodenal ulcer was made. This was not found at an urgent operation performed on the basis of these x-ray findings. Review of the films taught us that a minimal degree of deformity of the duodenum seen in a gastrointestinal series performed under emergency circumstances cannot be taken as positive evidence of ulcer. In 1 patient only the examination may have contributed to a recurrence of bleeding. This took place not in the X-Ray Department

only a slight deformity being present in the duodenum. Conservative therapy was persisted in and was successful in stopping the hemorrhage, the diagnosis was then further substantiated during a subsequent successful splenorenal anastomosis. In retrospect, if the very positive history of ulcer had been acted upon the patient would have received an unnecessary emergency operation.

Gastroscopy

Gastroscopy was performed as an urgent procedure only during second or repeated admissions of the patients in whom no source for the bleeding had been found by elective examinations during the previous periods of hospitalization. It was helpful in 2 cases, and perhaps should have been utilized more frequently.

TREATMENT

Conservative treatment as initiated on the medical ward did not differ in great extent from that in current practice in the United States. The pulse, blood pressure and blood counts were taken at frequent intervals depending upon the briskness of hemorrhage and the degree of shock. A chart of all stools and vomitus was made. If a history

of hematemesis or other vomiting within twelve hours of admission was obtained the patient was starved rather than fed. Similarly, patients with esophageal varices were not fed until the immediate bleeding and shock had been controlled. Feedings, when initiated, were of small amounts and of the softest types of foods. Careful sedation was carried out by the combined use of small doses of sodium luminal and various narcotics. Early in the series morphine was used rather extensively, but owing to the frequent vomiting that resulted from the use of more than 10 mg (1/6 gr) of this drug a shift to Demerol in 50-mg doses subcutaneously was made and found to be most satisfactory. The early recognition of the cirrhotic patient is most important, since minimal sedation is necessary in this group to avoid the precipitation of hepatic coma. Transfusions were the backbone of the replacement therapy and were given liberally not only to prevent shock but also to restore promptly a sufficient volume of blood so that the red-cell count would be elevated above 3,500,000. The parenteral injections of large doses of vitamins C and K were arbitrarily employed in patients with chronic peptic ulcer who had been on rigid feeding regimes for a long time. Fifty-three and 56 per cent, respectively, of the patients with and without ulcer stopped bleeding within twenty-four hours of admission. Forty per cent of the latter continued to bleed, compared to 21 per cent of the former. In 23 per cent of the patients with ulcer bleeding recurred after having once stopped, and only 1 nonulcer patient experienced a recurrence in bleeding. This is in keeping with our conception of bleeding from peptic ulcer—namely, that the reason for continuation of bleeding is the redigestion of the clot from the bleeding vessel by the strong acid and peptic secretion of the gastric mucosa in the patient with ulcer. A patient who stops bleeding early under medical treatment and then bleeds again may, from this data, be considered more likely to have a peptic ulcer than some other condition as a cause of his bleeding.

Surgical

Surgical operation was carried out in 10, or 18 per cent, of the patients with proved peptic ulcers. From a previous study of the literature (Warren and Lanman⁸) it was apparent that under the best conservative methods available there has always been an irreducible minimum of 1 or 2 patients out of every 20 with massive bleeding from ulcer who do not survive conservative therapy. These patients usually either are elderly or have some specific complicating factor besides the ulcer itself. We have considered it impossible to determine which of the patients in these groups is going to stop bleeding on medical therapy without spending many days in a therapeutic trial, which, if unsuccessful, leaves the patient in a poor state for

operation. We have adopted, as the result of our experience, a policy of operating at an early period on all patients over approximately forty years of age with bleeding from peptic ulcer that does not stop within forty-eight hours of entry or, having once stopped, begins again to an appreciable degree. In addition, operation was seriously considered on the basis of the same temporal indications when the diagnosis of extensive penetration was made or a complicating disease such as cirrhosis or diabetes mellitus was present. Wood⁹ has recently pointed out the high incidence of bleeding in diabetic patients with ulcer. This policy necessitates the inclusion in the operative group of many patients who would have stopped bleeding on a medical regime had it been continued. It is only justifiable, then, if it includes all the patients whose hemorrhage would not have stopped on a medical regime. This we believe to be the case with the exception of the rare patient who exsanguinates within forty-eight hours of admission.

We have believed that, to justify a policy of urgent operation on a selected group of patients, rigid requirements must be insisted upon. The diagnosis must have been confirmed by x-ray study and, to decrease the risk, the operation performed must be simplified in certain patients. For example, in comparison with the conventional gastric resection it may occasionally be considered wiser, in patients in whom the ulcer is very difficult to remove because it lies posteriorly in the gastroduodenal segment, to leave that ulcer in situ (Warren and Lanman⁸). In the latter instance, although it has not occurred in our experience, recurrent hemorrhage from the ulcer that has not been removed has been described (Welch¹⁰). We consider, however, that having performed such a procedure in a patient bleeding from duodenal ulcer and the ulcer having bled again, one is in a stronger position than if such a (first-stage) procedure had not been done. In the first place we have assurance that the ulcer will heal within a few weeks at the longest (McKittrick, Moore and Warren¹¹) and, secondly, if, rarely, further surgery seems advisable to stop hemorrhage, it can be done with the attention focused thoroughly on this objective. It helps the surgeon greatly to know that no gastrojejunal anastomosis need be done after eradication of the ulcer has been performed, and also that the patient can eat enough to maintain nutrition soon after operation. This is essential if liver disease is present.

The group of patients, all "proved" cases of ulcer, in whom the decision to operate was made, are shown in Table 3. The operations were graded as emergency when the patient's hemorrhage continued faster than replacement therapy could restore it, and urgent when bleeding was continuing but at a slow enough rate so that a red-cell count of 3,500,000 or higher could be restored before operation was begun. The 1 death, in a case of gastric ulcer

barium suspension was used, that the patient was examined in the prone and supine positions only, and that compression technic was not employed. Our indications for such emergency x-ray examination were as follows: persistent or recurrent bleeding in a patient on whom we were prepared to perform urgent surgery if the diagnosis of ulcer was definitely established, recurrent bleeding in a patient in whom previous studies had failed to determine the source of the hemorrhage. In each case the surgical member of the team agreed to the need of emergency x-ray examination, an adequate stock of matched blood for transfusions was on hand,

but six hours later on the ward, and was not fatal. Another patient, a man of fifty-six, entered the hospital with a massive hemorrhage and gave a history of having had a duodenal ulcer for years. To corroborate this he gave a history of having had a perforation sutured six months before and demonstrated an abdominal scar to prove it. Since he was in the older age group and did not respond to medical therapy within forty-eight hours, operation was strongly considered and planned. An emergency barium meal was thought by many to be superfluous in this case. It was performed, however, and large esophageal varices were seen,

BRILL'S DISEASE*

Report of 3 Cases with Aureomycin Treatment in 2

NATHAN BLUMBERG, M D † JOSEPH C DOANE, M D, ‡ AND LAURENCE B WEISS M D §

PHILADELPHIA

CASE REPORTS

BRILL'S disease should be considered as a cause of fever of undetermined origin in a general hospital that draws patients from the foreign-born population

Typhus fever, a scourge of all times and all nations, was first differentiated from measles in Italy by Jerome Cardan in 1536. Bravo, in 1570, and Fracastorius, in 1584, further described the disease, though the cause was not surmised. In 1608 Cober described the "Hungarian disease," which was prevalent in that army, and noted the presence of lice infestation among soldiers but did not relate them etiologically to what apparently was epidemic typhus. Five hundred and three years later, Nicolle discovered that the body louse could transmit this disease from monkey to monkey. He also observed that in a hospital where the patients' clothing was removed on admission no cases of typhus developed, except among the attendants who handled the discarded infested clothing.

Epidemic typhus accompanies war, and during World War I it was prevalent in Serbia, Germany, Austria, Russia and Poland. This type of typhus is caused by *Rickettsia prowazeki*, which utilizes the body louse as the vector. A second variety of the disease, known as endemic typhus, is constantly prevalent in the southeastern United States. This malady is somewhat milder than the former and differs in that the vector is the rat flea.

A mild sporadic variety of typhus was reported in 1898 by Brill¹ in New York. By 1910 this investigator had collected and reported 221 cases.² Zinsser,³ in 1934, reviewed the subject and suggested that patients who had once lived in an area where an epidemic of typhus fever had occurred and in whom clinical symptoms resembling typhus later developed were manifesting an exacerbation of a long-dormant typhus infection.

Three cases all in Russian-born persons admitted to the hospital with fever of undetermined origin, in which subsequent study established the diagnosis of Brill's disease are reported below. The patient in Case 1 was treated conservatively, whereas the latter 2 received aureomycin. The specific organism (*R. prowazeki*) was isolated in Cases 2 and 3.

CASE 1 S P, a 40-year-old housewife, was admitted to the hospital on June 21, 1948, with a chief complaint of fever and headache and discharged on July 13.

The present illness had begun 11 days prior to admission with vague prodromes of fatigability and irritability. The onset of fever occurred 4 days prior to admission. While the patient remained at home, the temperature varied from 101 to 104°F, and this was accompanied by headache and sweating. Her physician treated her with sulfonamides and penicillin without effect, and she was admitted to the ward service.

The past history revealed that in 1921, at the age of 13, the patient had migrated to America from Kiev, Russia. As far as she could recall she had had no serious febrile diseases either in Europe or in this country.

Physical examination showed a well developed and well nourished but dehydrated woman, who did not seem dangerously ill. The pupils reacted to light and accommodation. Slight conjunctival injection was present. The chest was normal except for bronchial breathing over the right lower lobe. There was no lymphadenopathy. Rectal and pelvic examinations were negative.

The temperature was 104.4°F, the pulse 94, and the respirations 26 per minute. The blood pressure was 128/80.

During the first 36 hours the temperature ranged between 101 and 104°F, and nonspecific drugs with cooling sponges comprised the therapy adopted. On the 3rd morning the temperature dropped to 98.6°F, and a macular rash was noticed on both upper extremities and over the sides of the abdomen. This spread during the day to include the arms, forearms, upper part of the chest and back. The rash became maculopapular and discrete. The lesions were reddish, with some brownish discoloration. Twelve hours after it was first observed, the rash faded, leaving only slight pigmentation. The patient again became febrile, the temperature ranging between 102 and 103°F, and continued so until the 6th hospital day when the temperature became normal and remained so until discharge.

On admission the patient was very irritable and complaining. On the morning of the 4th hospital day she became increasingly irritable, dull drowsy and apathetic. She was unresponsive and appeared exhausted. After defervescence, she became clearer mentally and gradually regained her appetite, and it was possible to maintain hydration without intravenous administration of fluids.

Röntgenologic examination of the chest showed the lungs to be clear and well aerated. The right hilar markings were accentuated but there was no evidence of pneumonitis. Electrocardiograms were normal.

Urinalysis and urine culture were normal on admission, but later after pyuria developed, microscopic examination showed many pus cells and a hemolytic *Staphylococcus albus* and *Aerobacter aerogenes* grew on culture.

Examination of the blood showed a red-cell count of 4,480,000, with a hemoglobin of 14.8 gm and a white-cell count of 10,350 with 76 per cent neutrophils, 1 per cent monocytes and 23 per cent lymphocytes. There were 71 per cent filamented and 29 per cent nonfilamented forms. During the course of the illness, the red-cell count dropped to 3,600,000, and the hemoglobin to 12 gm. The total white-cell and differential count remained stationary. The sedimentation rate was 54 mm per hour (Wintrobe method). The blood Wassermann test was negative. The blood sugar, urea nitrogen and total protein were normal.

Blood cultures on admission and on three subsequent occasions failed to reveal any organism. A stool culture showed only colon bacilli.

with severe portal hypertension, was the emergency case and has been discussed above. Of the 10 patients whose operations were regarded as urgent 4 had extensive penetrations with large inflammatory masses, 2 were complicated by liver or biliary-tract disease, and 1 was a diabetic patient. Two others were aged thirty-nine and sixty years, but had no specific complications of their duodenal ulcers. The tenth patient (J L S, Table 3) has been referred to above. It is impossible to estimate how many of these patients would have survived if conservative treatment had been continued, but from our previous clinical experience we believe that not over half the group would have survived.

DISCUSSION

From these studies our ability to make a differential diagnosis of upper-gastrointestinal-tract hemorrhage at the time of active bleeding on clinical grounds alone is limited. It can be made fairly accurately if one weighs carefully certain positive and negative findings of the history and physical examination. Two unusually helpful and accurate facts in the diagnosis of peptic ulcer in our series were a previous diagnosis of ulcer by a physician and the presence of pain during the bleeding episode.

Our attitude toward emergency x-ray examination is that it is the one indispensable maneuver in the diagnosis of the source of bleeding, but that although it is generally a safe procedure it is not necessary unless the x-ray findings are to change any course of therapy that has already been instituted. This obviously applies to its place in the selection of patients in whom surgical rather than medical therapy will be undertaken.

The majority of patients with hemorrhage of various degrees of severity continue to be successfully treated by conservative methods, the backbone of which is adequate blood replacement. Almost invariably the cases of ulcer in which the patients do poorly are those complicated by some additional disease. This may be vascular, hepatic or metabolic, but its prompt recognition by the internist is essential if he and the surgeon are to make an intelligent decision regarding the method of therapy. Thus, an earlier and more radical

surgical approach to the bleeding ulcer complicated by arteriosclerosis, cirrhosis or portal hypertension, diabetes or penetration resulted in a lower mortality than we believe would have occurred had such a policy not been in effect.

SUMMARY

A combined medical and surgical team directed therapy in 86 cases of massive upper gastrointestinal hemorrhage, 56 of which were due to peptic ulceration. The mortality of the patients with ulcer was 3.6 per cent, and that of the nonulcer bleeders 30 per cent.

Emergency gastrointestinal x-ray films were taken when the course of the bleeding or the presence of certain complications suggested that urgent operation might be performed if the presence of an ulcer as the source of the hemorrhage could be definitely established. Satisfactory x-ray films were obtained in 17 actively bleeding patients, and in only 1 case was the bleeding possibly aggravated by the procedure.

Urgent operation was successfully carried out in 9 cases after the establishment of a definite diagnosis of peptic ulcer. An additional patient was operated on as an emergency, and died two days postoperatively. These patients had been selected because of continued bleeding over forty-eight hours, age or the presence of certain complicating diseases, notably portal hypertension.

This was the fifth case of suspected Brill's disease studied by the Army Epidemiological Board working at the Laboratories of Harvard School of Public Health in which rickettsial identification justified a positive diagnosis

CASE 3 M T, a 55-year-old contractor, was admitted to the hospital on April 21, 1949, with the chief complaint of chills and fever

On March 27 the patient had been discharged from the Jewish Hospital after a colectomy and ileosigmoidostomy for carcinoma of the colon Three weeks after discharge, during the convalescent period following his operation, he had become ill with the present illness Four days prior to admission, he had noted malaise and increasing weakness On the next day, the temperature was 105°F, and he suffered severe shaking and chills During the next 48 hours, he became increasingly toxic, the temperature remaining between 101 and 105.6°F He complained of severe headache. He was admitted to the Jewish Hospital on the 4th day of fever

Thirty-seven years previously in Galicia, Poland, he had had an epidemic illness of several weeks' duration, with chills and fever It is assumed that this was typhus, which was prevalent in eastern Europe at that time. He emigrated to the United States at the age of 19

Physical examination showed a severely toxic patient whose condition resembled the so-called typhoidal state The temperature was 102.8°F, the pulse 120, and the respirations 26 He was irritable and confused The chest was clear except for transient rales at the right infrascapular area The abdominal wounds in the right lower and left lower quadrant were indurated but showed no evidence of infection Rectal examination was negative except for marked irritation around the anus

Early the next morning, a discrete maculopapular rash was noted on the trunk During the day, this spread to the back and the upper and lower extremities It did not involve the palms or soles The lesions blanched on pressure and were slightly pigmented The patient remained febrile and toxic and complained of headache In view of the history of a febrile illness in his native country and the sustained fever, chills, headache, mental state and rash, the diagnosis of Brill's disease was suggested

On the morning of the 6th day of fever, after appropriate laboratory tests had been made, aureomycin was administered orally That afternoon, the rash began to fade, and 24 hours after the administration of the drug, the skin was clear except for the axillary areas and the dorsa of the feet, within 48 hours, it had virtually disappeared Twenty-four hours after the start of aureomycin, the patient was improved His appetite was better, he was able to take some food, and his mental attitude changed Because of the ileosigmoidostomy, camphorated tincture of opium was given to prevent the too rapid passage of the aureomycin through the bowel Forty-eight hours after the beginning of specific therapy, on the 8th day, the temperature fell to normal and he was markedly improved Improvement continued until discharge from the hospital on the 13th day

Aureomycin was begun in doses of 250 mg every hour for three doses and then every 2 hours until he became afebrile. The drug was continued every 4 hours for 24 hours and then for every 6 hours for 48 hours He received a total of 10 gm of aureomycin orally

On admission the red-cell count was 4,100,000 with 12 gm of hemoglobin, and the white-cell count was 9300, with 46 per cent neutrophils, 4 per cent monocytes and 10 per cent lymphocytes There were 20 filamented and 80 nonfilamented forms Urinalysis, the blood urea nitrogen and a blood culture were negative. Roentgenographic examination of the chest showed the lung fields to be normal There was no evidence of metastasis or other tumor

Capsules containing lice were implanted on this patient on the 6th day, and subsequent animal study was successful in isolating the rickettsias

Agglutination tests for *E. typhosa* O and H, paratyphoid A, paratyphoid B, brucellosis and *P. OX-19* were negative on the 5th and 8th days of fever

Complement-fixation tests with the specific antigens of epidemic and murine typhus were done at the Virus Diag-

nostic Research Laboratory of the Children's Hospital, Philadelphia The results are presented in Table 3

This patient had been convalescing at home after an operation and had no possibility of becoming infected by the vectors of typhus The isolation of the causative rickettsia,

TABLE 3 Complement-Fixation Tests in Case 3

together with the complement-fixation tests, indicated the diagnosis of Brill's disease

DISCUSSION

It is to Brill^{1, 2} and Zinsser^{4, 5} that the current concepts of this clinical entity are due It had previously been assumed that this disease was related to the murine or endemic typhus described by Maxcy⁶ as occurring in Mexico and the southeastern United States

Between 1910 and 1933, in New York and Boston, 538 cases of Brill's disease were observed About 95 per cent of these cases occurred in foreign-born persons, 93.6 per cent of whom had been born in the endemic typhus regions of Europe, with 80 per cent from Russia alone About 90 per cent of the patients were Jewish This preponderance is easily understood if one realizes that in that period immigration to this country consisted largely of the Jewish populations of the regions It was also clear that patients in the second decade studied were about ten years older than those in the earlier group None of the cases could be traced to the usual vectors, and it was shown that almost every patient was from a different home

From bacteriologic studies, Zinsser ascertained that the virus of Brill's disease behaved like the European type He concluded that a certain percentage of patients who have had typhus at an early age remain clinically well for years, but during this time are carriers of the disease and may later suffer a second attack This variety of typhus is now named Brill's disease.

Blatteis⁷ reported a series of 138 cases of this disease and confirmed Brill's observations Ninety-five per cent of his patients were Jewish immigrants from Russia None of the cases could be traced to exposure, and none of the hospital personnel contracted the disease, although no special precautions were taken Lewis,⁸ at the Pennsylvania Hospital, reported 13 cases with similar observations

Morgan et al.⁹ recently described 2 cases of Brill's disease occurring in Irish-born immigrants who had lived in Boston for over thirty years The possibility of recent infection was ruled out so that the

The spinal fluid obtained at the height of the mental torpor was clear with a count of 9 lymphocytes per cubic millimeter. Culture failed to reveal any pathogens.

Attempts were made, beginning on the 9th day of fever, to isolate the causative rickettsia. Several samples of whole blood, the buffy coat of spun-down citrated blood and a bone-marrow specimen obtained from the sternal marrow were injected into animals. Three colonies of lice enclosed in special capsules were allowed to feed on the patient for varying periods, and animal inoculations were then done.

Isolation attempts by all these methods were unsuccessful. No rickettsia could be demonstrated.

Agglutination tests for *Eberthella typhosus* (strains O and H), paratyphoid A, paratyphoid B, brucellosis and *Proteus OX-19* were negative on admission and again 2 days later. On the 14th day of fever the agglutination for *P. OX-19* became positive in a titer of 1:320. On the 23rd day the titer increased to 1:640.

At the Virus Diagnostic Research Laboratory of the Children's Hospital of Philadelphia, complement-fixation tests were performed with the following results: the titers for epidemic typhus and murine typhus were, respectively, 1:64 and 1:16 on the 7th day and 1:2048 and 1:512 on the 15th day.

Confirmation was obtained by serologic studies made by the Army Epidemiological Board working at the Laboratories of Harvard School of Public Health under the direction of Dr. Edward S. Murray, who reported the results shown in Table 1. Thus there was serologic evidence of infection with the rickettsia of epidemic typhus.

She gradually regained her strength and well being and had no sequelae, with the exception of a mild pyuria begin-

ning on the 15th day, undoubtedly subsequent to the repeated catheterizations.

She was seen for a follow-up examination 2 months after discharge and was clinically well.

Since the patient had had no recent exposure to the known vector of epidemic typhus this was assumed to be a case of Brill's disease.

CASE 2. A F, a 41-year-old locksmith, was admitted to the Medical Service on January 22, 1949.

This patient had been well until 5 days before admission, when he complained of a toothache. On the following day he developed a headache, which persisted, together with malaise, nausea, vomiting and fever. Associated with these symptoms were abdominal distention and pain. On the next day, the temperature varied between 103° and 105°F. Three hundred thousand units of penicillin was administered daily for 4 days along with a sulfonamide. When seen at home by one of us just prior to admission, he presented a picture of febrile toxicity, the cheeks were flushed, the eyes dull, and the appearance then was strongly suggestive of typhoid fever. A fine reddish macular rash, which blanched on pressure, was observed on the trunk. Mouth hygiene was poor, and the gums bled easily on pressure. There was evidence of a pneumonitis at the right base. The abdomen was moderately distended, but no masses were felt.

Later that day, the patient was admitted to the hospital, and a more careful history and physical examination were possible. He complained of pains over the frontal area, beneath the sternum and generally over the abdomen. He was quite dehydrated, and the rash on the abdomen seemed more diffuse than it had been a few hours earlier. The edge of the liver was just palpable beneath the costal margin. A provisional diagnosis of septicemia arising from an infected tooth, virus pneumonitis or a rickettsial disease was made.

It was further learned that the patient had been born in Kiev, Russia, and that at the age of 6 he had contracted either typhus or typhoid fever, probably the former. He had been entirely well until the present illness. He had come to the United States at the age of 16. His locksmith shop was located adjacent to a pet shop, where mice and rats were sold. With this history, the attention of the examining physician turned to the possibility that the patient was suffering with recrudescence epidemic typhus fever (Brill's disease).

On the next day, the toxicity persisted, the temperature remaining high (103°F) and the pulse 100 per minute. On the 3rd day after admission, the rash seemed to fade on the abdomen but was still present on the arms and the legs. Lice colonies were implanted on the patient by Dr. Edward S. Murray, of the Army Epidemiological Board, working at the Laboratories of Harvard School of Public Health. Aureomycin was then begun on the 8th day of illness. One thousand milligrams was given for the first dose, followed by 750 mg every 6th hour for 2 days, 500 mg every 6th hour for 3 days and 250 mg at like intervals for the next 2 days. In all, 13 gm of aureomycin was administered over an 8-day period. The temperature fell to 100°F 14 hours after the beginning of aureomycin therapy, but in the next 10 hours it rose to 104°F, remaining so for 8 hours, and then rapidly declined to normal on the 10th day of the disease. The patient continued to improve rapidly, was allowed out of bed on the 14th day and was discharged on February 6.

On the day after admission the red-cell count was 4,470,000, with 11.8 gm of hemoglobin, and the white-cell count was 12,350, with 73 per cent neutrophils, 23 per cent lymphocytes and 4 per cent monocytes. A count of filamented and nonfilamented forms showed a marked shift to the left. The blood urea, chloride and sugar were within normal limits. Blood cultures repeated on three occasions were negative. Roentgenologic examination of the chest at the time of admission showed increased bronchovascular markings. A plain film of the abdomen was normal. An electrocardiogram showed a sinus tachycardia. Smears from the gums were positive for Vincent's organisms. A stool was negative for ova and parasites.

Capsules containing lice were implanted on this patient on the 7th day of illness for 13½ hours. Subsequently, these lice were placed on a normal rabbit for 11 days. At the end of this time, 120 lice remained alive. These were ground up and injected intraperitoneally into x-ray cotton rats. Five days later the rats were very sick, were killed and

TABLE 2 Complement-Fixation Tests in Case 2

DAY OF TEST	EPIDEMIC TYPHUS TITER	MURINE TYPHUS TITER
7th	1:512	1:128
10th	1:2048	1:1024
16th	1:2048	1:1024

smears from their peritoneal exudate showed large numbers of intracellular and extracellular organisms, which when stained by the Macchiavelli method were recognized as typical rickettsias. These rickettsias are now being further studied with immunity and other animal methods to differentiate them from murine-typhus strains. It seems from the clinical picture of this patient and from his history, that these rickettsias will be identified as the specific etiologic strain causing recrudescence epidemic typhus.

On admission the agglutination tests for *E. typhosa* O and H, paratyphoid A, and paratyphoid B, *Brucella abortus* and *P. OX-19* were negative. On the 10th day of illness, the agglutination for *P. OX-19* was ++++ and ++++, respectively, in dilutions of 1:20 and 1:40. On the 12th day of illness, the agglutinations for *P. OX-K* and *OX-2* were negative from a titer of 1:20 through 1:1280. On the 15th day of illness, tests for *P. OX-19* were positive in 1:320 dilution. On the 20th day of illness tests for *P. OX-19* were positive in dilutions of 1:20 to 1:80 but negative in dilutions of 1:160 to 1:320.

Serum was sent to the Virus Diagnostic Research Laboratory of the Children's Hospital, where complement-fixation tests were performed and the results shown in Table 2 were obtained.

ARTANE IN THE TREATMENT OF PARKINSON'S DISEASE

A Report of Its Effectiveness Alone and in Combination with Benadryl and Parpanit

ROBERT S. SCHWAB, M.D.,* AND WILLIAM R. TILLMANN, M.D.†

BOSTON

THIS report is a clinical evaluation of a recently synthesized drug called Artane† in 44 cases of Parkinson's disease. Artane is a piperidyl with the formula shown in Figure 1, on which also are written the structural formulas of Benadryl and Parpanit for comparison. These three chemicals are not similar in structure to either atropine or scopolamine.

The details of the chemical behavior and the pharmacologic and physiologic effects of the drug in animals are available in the reports of the manu-

the therapy of Parkinson's disease with the newer drugs.

By means of such a chart it is possible gradually to reduce the medication that the patient is taking when first seen and, at the same time, slowly to increase the dose of Artane. Sudden withdrawal of the antispasmodic effects of the atropine drugs is avoided by this means. A further advantage of such gradual overlapping of medication is the knowledge of the value in a particular patient of the two drugs together.

FIGURE 1 Comparative Structural Formulas of Artane, Benadryl and Parpanit

facturer and will be published shortly. It is safe to use, has no serious side effects, is promptly eliminated and has no disturbing effects on the blood or the renal or cardiac system.

The hourly schedule chart devised by Viets and Schwab¹ and in use in the treatment of patients with myasthenia gravis is extremely valuable in

An example of the regulation by slow reduction of the belladonna drug and increase in Artane is shown in Figure 2 and in the following case:

A 44-year-old woman with a history of severe influenza in 1919 and the onset of slowness in motion of the left arm 5 years before reporting for treatment had had involvement of the left leg and stiffness, fatigue and loss of fine movements in the fingers for 4 years. The tremor, first in the fingers and later in the wrist, had been present for 3½ years. For 1 year slight involvement in the right arm had been observed. The diagnosis of Parkinson's disease had been made at the onset by her family physician, and scopolamine, stramonium and amphetamine sulfate had been given in the usual doses.

*Supplies of Artane used in this investigation were furnished by the Lederle Company Pearl River New York.

disease probably represented the recrudescence of a previous infection

During the recent war, new epidemics of typhus swept Europe and Asia. Troops operating in these areas were protected better than ever before by means of new insecticides, careful immunization and rigid quarantine of existing cases. In fact, during the recent war, Gordon¹⁰ reports that only 3 confirmed cases of typhus occurred in the American troops in the European Theater of Operations. All experienced mild attacks. Two returned prisoners of war also were found to have typhus. Scoville¹¹ states that in the Japanese-Korean areas only 28 cases occurred in the occupation forces while an epidemic was raging in those countries. All patients had been vaccinated, and the disease was mild. No deaths resulted. It is surmised that some of the victims of these new epidemics may continue to harbor the organism, resulting in an increased incidence of Brill's disease years hence.

Aureomycin, an antibiotic derived from *Streptomyces aureofaciens*, holds promise of value in this and similar diseases. At the panel meeting of the New York Academy of Sciences held on July 21, 1948, the use of this drug was reported in rickettsial diseases of many types.

Wong and Cox¹² discussed the use of aureomycin in guinea-pig inoculations with *R. prowazeki*. When the drug was started before the febrile reaction to the inoculations had occurred, the fever was aborted. If the medication was begun after the onset of fever, the case was controlled in twenty-four to forty-eight hours, whereas the control animals had fever for approximately seven days.

Anigstein, Whitney and Beninson¹³ confirmed this with similar studies using guinea pigs. Both oral and parenteral administrations of the drug were effective.

Schoenbach, Bryer and Long^{14, 15} reported a case of Brill's disease in which therapy was started on the sixth day. Within forty-eight hours, the patient had become afebrile and asymptomatic.

In the study of a case of fever of undetermined origin, Brill's disease should be considered.

Fever, malaise, intense headache, chills, a skin rash and mental signs occurring in a foreign-born person years after his arrival from an area where epidemic typhus was present should cause one to consider this diagnosis. As previously noted by Schoenbach et al.¹⁵ and again emphasized here, the Weil-Felix reaction cannot be used to exclude this disease. Agglutinations with the specific antigens of epidemic and murine typhus are necessary.

Confirmation of the diagnosis is made by serologic study and growth of the rickettsias on blood culture. Plotz¹⁶ recently studied 23 cases of Brill's disease by means of complement-fixation tests. He found that the serums of the patients gave higher titers with the antigen of classic epidemic typhus than with that of murine typhus, thus lending addi-

tional support to Zinsser's hypothesis. Biopsy of skin lesions may also demonstrate the rickettsias.

Probably one of the reasons for failure to isolate the organism in Case 1 was that lice studies and the withdrawal of blood specimens were not started before the ninth day of the disease, and Murray¹⁷ has found that the ninth day is too late in the course of Brill's disease to obtain the strain.

These 3 cases demonstrate clearly the value of aureomycin in Brill's disease. In Case 1, in which the patient was treated conservatively, spontaneous remission occurred on the eleventh day. In Case 2 aureomycin was begun on the eighth day, and remission occurred on the tenth day. In Case 3 the drug was started on the sixth day, and remission occurred on the eighth day. Early diagnosis with prompt administration of aureomycin leads to a dramatic remission within forty-eight hours.

SUMMARY

Three cases of Brill's disease occurring in persons born in Russia, 2 of whom had a history of epidemic typhus years previously, are presented.

The patients were admitted with a diagnosis of fever of undetermined origin, and all the usual studies were negative.

The final diagnosis of Brill's disease was made by a careful history, serologic study and isolation of the organism.

Oral administration of aureomycin was used in the treatment of two cases with prompt clinical improvement.

We are indebted to Dr. Edward S. Murray, of the Army Epidemiological Board, working at the Laboratories of Harvard School of Public Health, who gave his time, efforts and advice in the special studies. Acknowledgment also is made to Dr. M. Michael Sigel, of the Virus Diagnostic Research Laboratory of the Children's Hospital of Philadelphia, who performed the complement-fixation tests in all 3 cases.

evaluation (ten points were used in the evaluation of these cases), large numbers of cases, placebo substitution, a long period of treatment, observation by different physicians (three different observers were involved in this investigation), different groups of patients (three separate groups were reported), adequate time on single drugs, a shift in drugs and multiple drugs and specific psychotherapy.

A truly efficient drug should be effective in any hands and not be subject to the individual aptitudes of the investigator. No such remedy is known today, and unless each patient is individually adjusted and frequently and carefully followed, with necessary alterations in dosage schedules, no better results will be obtained with these new compounds than with hvoscine alone.

The effectiveness of Benadryl as a remedy for the symptoms of Parkinson's disease has been confirmed, but the drug is less effective alone than either Parpanit or Artane (2 out of 9 cases). Benadryl in combination with Artane or Parpanit or

even atropine drugs was effective in 12 of 24 cases in which it was tried.

The effect of other antihistaminic drugs, such as Thephorin, aminophylline and Benadryl mixture (Dramamine) is in the process of evaluation.

SUMMARY

The effect of Artane alone and in combination with other drugs in alleviation of the symptoms of Parkinson's disease is reported in 44 cases. Favorable results were obtained in 67 per cent of cases in which treatment with Artane was given.

ABDOMINAL PAIN IN HEMOCHROMATOSIS*

GERARD DESFORGES, M.D.†

BOSTON

AMONG the various manifestations of hemochromatosis are sometimes found certain symptomatic and objective features that simulate acute abdominal conditions. Writers in the medical literature in the United States have given scant notice to the finding of abdominal pain in this disease. Boland and Curran¹ presented one of the few reports of such abdominal symptomatology in hemochromatosis occurring in two brothers. The first entered the hospital with signs and symptoms suggesting cholecystitis. Cholecystectomy was performed, and on pathological examination the gall bladder was found to be normal. However, observation of a brown, cirrhotic liver at operation led to skin biopsy, and the diagnosis of hemochromatosis was made. The patient died on the ninth hospital day in hepatic coma. Later, his brother entered the hospital with similar symptoms. In view of the previous family history, laparotomy was not performed, and skin biopsy again revealed hemochromatosis. The patient recovered with the aid of symptomatic and supportive measures. Hurxthal² reported a case of hemochromatosis, proved by biopsy, that showed marked impairment of renal and adrenal function. Without comment he noted that about one week before admission the patient had had abdominal cramps and diarrhea.

In contrast to the infrequency with which such findings have been reported by American authors is the statistical analysis of the French author Boulin,³ who noted that in 70 cases 34 per cent of patients were originally admitted to the hospital because of painful abdominal crises, those located in the gall-bladder region being especially severe. He pointed out that these patients may even present pseudo-obstructive crises. Furthermore, he stated that spasm of the colon may at times be demonstrated by x-ray examination. In his general review Sheldon⁴ cited an incidence of 6 per cent of patients who showed abdominal pain, 1 per cent having the symptoms with the onset of pigmentation.

Abdominal pain in itself is not an unusual feature of other types of liver cirrhosis, particularly during failure.^{5,6} This pain is not usually associated with tenderness, however. Furthermore, its prognostic implications do not appear to be as immediately ominous as those in the cases presented below, in which the patients died soon after the onset of the abdominal symptoms.

Interest in this subject was stimulated on performance of the autopsy in Case 1. This patient entered the hospital with an abdominal picture that baffled both the medical and surgical services on which he was studied.

*From the First (Tufts) Surgical Service, Boston City Hospital.

†Junior assistant resident, First (Tufts) Surgical Service, Boston City Hospital.

For the past year she had been given Rabellon, 2 tablets four times a day. These belladonna drugs gave her some relief, but produced so much dryness of the mouth, blurred vision and depression of energy that she was thoroughly discouraged.

On the 3rd day of treatment with Artane the patient was relieved of her previously disturbing side effects, and noted a clear-cut increase in motor function, and the loss of fatigue. Rigidity was reduced, and there was a definite elevation of her mood and outlook. On the 7th day the $1\frac{1}{2}$ tablets of Artane (3 mg) produced a mild giddiness with blurred vision that was transient so that she went back to the 2-mg dose every 3 hours according to the instructions given at her first visit.

When seen 2 weeks later she showed objectively less rigidity and tremor—more rapid movements in her fingers, better posture and was subjectively 50 per cent improved (toward her pre-illness status). Objectively by the various tests used she was 25 per cent better than on the belladonna drugs.

A month later, her improvement maintained, she was given Benadryl 50 mg four times a day in addition to Artane, and when seen 6 weeks later she was 5 to 10 per cent better both objectively and subjectively than on Artane alone.

Artane is effective in different dosages in different patients. Overdosage produces side effects similar to those of Parpanit, such as giddiness,

DISCUSSION

In spite of the promising results of the newer belladonna preparations introduced from 1938 to 1942 such as Bulgarian belladonna root, Rabellon, Vinobel, Neoscopolamine and various mixtures, the treatment of Parkinson's disease has not been entirely satisfactory to the patient or the physician. The unpleasant and disturbing side effects, such as dryness of the mouth and blurred vision, occurred with all these compounds. In June, 1948, Budnitz² reported very favorable results with the antihistamine Benadryl, confirmed by Ryan and Wood.³ In March, 1949, Schwab and Leigh⁴ described success with a new synthetic drug, Parpanit. Neither of these substances produced the degree of drying of secretion or interference with accommodation encountered with atropine drugs.

The effectiveness of a treatment against the symptoms of a disease usually varies inversely with

dryness of the mouth, blurring of vision and headache. The initial dose is half a tablet, or 1 mg, four times a day. This is gradually increased until the patient is taking 3 mg five times a day as a high level. The average is 2 mg five times a day.

Artane has been found less toxic than Parpanit in older patients, but it is less effective in reducing tremor. Indeed, in some patients, the tremor is worse in spite of the reduction in rigidity. Of 44 patients who had received Artane for over three months, only 7 (16 per cent) were relieved sufficiently, as compared to their status on atropine, to remain on Artane alone. Nine required the addition of Parpanit, and 7 were best regulated on a combination of Artane and Benadryl. Six others fared best on atropine drugs and Artane.

Twenty-nine, or 67 per cent, were 20 to 30 per cent better after such regulation on Artane than on the medication previously given. Seven were no better, and 8 could not tolerate Artane alone or in combination. Artane was therefore a failure in 33 per cent.

the number of remedies in use. In diabetes, for example, the 90 to 100 per cent success achieved by insulin has led to its replacing other forms of treatment. In Parkinson's disease, in which only 20 to 30 per cent relief of symptoms is possible, over a dozen different medications as well as surgical operation, are available. These newer chemicals do not, unfortunately, alter this deficit, and Artane is not in any sense an "insulin" for these chronic sufferers.

Since the relief of symptoms is only partial in Parkinson's disease, it is not an easy matter to draw accurate comparative results with the newer drugs and the older atropine mixtures. The course of the disease may be affected by spontaneous variation, rest in hospital, special attention, the influence of the observer on the patient, sedative effects, learning curves, enthusiasm of the observer, influence of new tests or drugs, favorable medical changes and effects of concomitant treatment. Greater accuracy may be obtained by objective as well as subjective reports, multiple points in

hemochromatosis whose signs of heart failure disappeared with cortin therapy. Indeed, in the early phases hemochromatosis is most often confused with Addison's disease.^{3, 15} The appearance of diabetes mellitus is a major aid in pointing to the true disease, for primary adrenal insufficiency is extremely rarely associated with diabetes.¹⁶

Since the death of these patients in congestive failure caused by extensive deposition of hemosiderin in the myocardium is now a recognized entity,^{17, 18} pain due to passive congestion in abdominal viscera is a possibility. Hemosiderin deposition may also result in abnormalities in cardiac rhythm,¹⁹ making the patients candidates for embolic phenomena.

Liver failure per se may be the cause of severe abdominal pain.²⁰ However, this is one of the unusual manifestations of this rare disease.

Pancreatitis must also be considered in the differential diagnosis of abdominal pain. In the cases reported above, however, there was no pathological evidence that the pancreas was the cause of the symptoms.

Other painful manifestations of hemochromatosis, such as pain in the extremities,²¹ precordial episodes simulating myocardial infarction but without morphologic findings at post-mortem examination¹⁸ and spasm of the large bowel,² suggest a common etiology in isolated episodes of vasospasm or colic, owing to the immediate effects of hemofuscin deposition in smooth-muscle cells of arteries and of the alimentary tract.²²

Finally, pain in the abdomen in this disease may be a manifestation of abnormalities in glucose metabolism. In hypoglycemia, abdominal pain is possibly due to parasympathetic activity manifested by increased contraction of various segments of the gastrointestinal or biliary tract.²³ Ketosis, which may also be accompanied by acute abdominal pain, tenderness, nausea and vomiting, may be an especially dangerous pitfall because of the often associated abdominal muscular rigidity, leukocytosis and fever.²⁴ In diabetes as difficult to control as that of hemochromatosis, hypoglycemia and ketosis are perennial threats.^{24, 25}

SUMMARY

Attention is called to a clinical syndrome of abdominal pain in hemochromatosis that has been

mentioned very rarely in the medical literature in the United States.

Three autopsied cases showing no morphologic basis for the abdominal episodes are reported. Several possible explanations of this syndrome are presented.

I am indebted to Dr. Frederic Parker, Jr., for his assistance and valuable suggestions.

Examination of the Boston City Hospital records revealed that in the period between 1936 and 1946 there were 40 cases of hemochromatosis proved by autopsy at this hospital. Of these, abdominal pain was a prominent feature of the clinical course in 6. Three had demonstrable causes for the symptom, 1 had liver failure, 1 had a hepatoma, and 1 had a ruptured diverticulum with peritonitis. The remaining 3 had no morphologic background as a basis for the bizarre abdominal symptomatology. These cases are presented below.

CASE REPORTS

CASE 1 F L, a 41-year-old man, had the diagnosis of diabetes mellitus made in October, 1945. Diet and insulin controlled the diabetes. A few weeks later he experienced upper abdominal pain, nausea and vomiting for 3 days. Several months later there was a recurrence of this pain, described as dull, continuous and nonradiating. On the evening of entry, there was an increase in the severity of the epigastric pain, without radiation. There was some nausea but no vomiting.

Physical examination revealed a well developed, middle-aged man in evident distress. The liver edge was half way between the costal margin and the umbilicus. The entire epigastrium was tender.

The blood pressure was 100/90. The temperature was 98°F, the pulse 114, and the respirations 20.

Laboratory work showed a yellow sugar reduction in the urine. The white-cell count was 14,400. The blood sugar was 265 mg per 100 cc. The carbon dioxide combining power was 45 vol per cent.

Treatment with parenteral injection of saline solution was inaugurated within the first 10 hours. The blood sugar values rose to 450 mg per 100 cc, and during this period a total of 100 units of regular insulin was given. Ten hours after admission there was a green sugar reduction in the urine, but a + acetone test was noted for the first time. The blood chloride on the day after entry was 105 milliequiv per liter (after 2300 cc of saline solution had been given intravenously). The blood sugar fell to 130 mg per 100 cc, and the carbon dioxide combining power to 38 vol per cent. From the time of admission, a shock-like picture developed progressively in spite of plasma and saline administration. About 28 hours after entry the patient was treated for possible adrenal failure. Thirty cubic centimeters of adrenal cortical extract (Upjohn's aqueous extract) and 1500 cc of 1.5 per cent saline solution were given. The patient rallied, and the blood pressure returned to audible limits at 80/60. No further cortical extract was obtainable, and he died 36 hours after admission.

Autopsy (46-57) revealed extensive hemochromatosis involving the liver, pancreas, heart, lungs, kidneys, spleen, bone marrow, lymph nodes, pituitary body and thyroid and adrenal glands. There was no morphologic explanation for the abdominal pain or sudden death.

CASE 2 J F, a 47-year-old man, entered the hospital in June, 1937, with pneumonia. Hepatomegaly and urinary findings indicative of diabetes mellitus were noted. The pneumonia cleared rapidly, and an insulin regimen was instituted. He left against advice 6 days after admission. In January, 1938, he returned for regulation of the insulin dosage. This was found to be quite difficult. Skin biopsy confirmed the suspicion of hemochromatosis. In May, 1938, the patient returned again with midabdominal, cramping pain of 4 days' duration.

Physical examination revealed a well developed, poorly nourished man in no acute distress. The liver extended one handbreadth below the costal margin. There was diffuse abdominal tenderness.

The blood pressure was 130/85, the temperature 98°F, the pulse 80, and the respirations 20.

Laboratory studies showed a green sugar reduction in the urine in addition to a trace of albumin and a + test for bile. The red-cell count was 3,750,000 and the white-cell count was 7200. Blood chemical studies revealed a fasting blood sugar of 267 mg per 100 cc.

The patient showed signs of progressive cardiac decompensation and transitory episodes of fibrillation. On digitalis, ammonium chloride and fluid restriction he made rapid improvement and left against advice 2½ weeks after admission. Within 2 weeks he was readmitted with evidence of dehydration and diabetic coma. He died within 36 hours in spite of vigorous supportive measures.

Autopsy (38-316) showed marked hepatomegaly and evidence of hemochromatosis in the liver, kidney, pancreas and heart.

CASE 3 W T, a 58-year-old man, entered the hospital in April, 1933, with signs and symptoms of scurvy, for which he was treated successfully. In September, 1939, he returned with signs of congestive failure. Four months before his final admission, he returned again with cardiac decompensation, when a diagnosis of arteriosclerotic heart disease with auricular fibrillation was made. The last admission, on February 23, 1945, was again because of cardiac decompensation.

Physical examination showed a middle-aged man in acute distress with orthopnea and dyspnea. There were crackling rales and dullness at the lung bases. The liver edge was palpated four fingerbreadths below the costal margin. Pitting edema of the legs was evident. Slight scleral icterus was noted.

The blood pressure was 112/76. The temperature was 98°F, the pulse 120, and the respirations 26.

Examination of the urine revealed a ++ to +++ test for albumin and a + to ++ test for bile, and the sediment contained occasional red and white cells. The non protein nitrogen was 44 mg, and the fasting blood sugar 115 mg per 100 cc. Studies of liver function demonstrated impairment.

The patient was treated with digitalis, a salt-free diet and ammonium chloride. On this regimen he became asymptomatic and was allowed out of bed on the 4th day. On the 12th hospital day he suddenly complained of abdominal pain and went into a state of peripheral vascular collapse. Twelve hours later he had a similar attack of pain and died. The clinical impression was pulmonary infarction.

Autopsy (45-127), performed 5 hours post mortem, showed arteriosclerotic heart disease, rheumatic heart disease with involvement of the aortic valve, and hemochromatosis involving the heart, lungs, liver, spleen, pancreas, kidneys, gastrointestinal tract, lymph nodes, thyroid, adrenal and parathyroid glands, testes, bone marrow, skin and pituitary body. There was no demonstrable morphologic cause for the pain or sudden death.

DISCUSSION

Many hypotheses can be offered as reasons for these symptoms. One of the most attractive possibilities to account for the episodes of abdominal pain in hemochromatosis is adrenal cortical insufficiency. This symptom, according to Soffer,⁷ occurs in a relatively small percentage of patients with Addison's disease in the intercritical period, but crises are often heralded by gastrointestinal manifestations, including abdominal pain. Adrenal involvement as one of the multiple endocrinopathies of hemochromatosis seems well established.^{2,4,8} Hurxthal's² case is an example. The patient of Layan,⁹ a twenty-nine-year-old man whose pigmentation cleared on massive doses of vitamin C, is possibly another. A relation has been shown between adrenal cortical extracts and vitamin C,¹⁰ and between vitamin C and secretion of adrenal cortical hormones under stress.^{11,12} Moreover, the first case reported above suggested a therapeutically diagnostic response to the adrenal cortical extract administered. Evidence of the same nature is afforded by the report of Oumansky and Longuet¹⁴ in an eighteen-year-old girl with

hemochromatosis whose signs of heart failure disappeared with cortin therapy. Indeed, in the early phases hemochromatosis is most often confused with Addison's disease.^{3, 15} The appearance of diabetes mellitus is a major aid in pointing to the true disease, for primary adrenal insufficiency is extremely rarely associated with diabetes.¹⁶

Since the death of these patients in congestive failure caused by extensive deposition of hemosiderin in the myocardium is now a recognized entity,^{17, 18} pain due to passive congestion in abdominal viscera is a possibility. Hemosiderin deposition may also result in abnormalities in cardiac rhythm,¹⁹ making the patients candidates for embolic phenomena.

Liver failure per se may be the cause of severe abdominal pain.²⁰ However, this is one of the unusual manifestations of this rare disease.

Pancreatitis must also be considered in the differential diagnosis of abdominal pain. In the cases reported above, however, there was no pathological evidence that the pancreas was the cause of the symptoms.

Other painful manifestations of hemochromatosis, such as pain in the extremities,²¹ precordial episodes simulating myocardial infarction but without morphologic findings at post-mortem examination¹⁵ and spasm of the large bowel,² suggest a common etiology in isolated episodes of vasospasm or colic, owing to the immediate effects of hemofuscin deposition in smooth-muscle cells of arteries and of the alimentary tract.²²

Finally, pain in the abdomen in this disease may be a manifestation of abnormalities in glucose metabolism. In hypoglycemia, abdominal pain is possibly due to parasympathetic activity manifested by increased contraction of various segments of the gastrointestinal or biliary tract.²³ Ketosis, which may also be accompanied by acute abdominal pain, tenderness, nausea and vomiting, may be an especially dangerous pitfall because of the often associated abdominal muscular rigidity, leukocytosis and fever.²⁴ In diabetes as difficult to control as that of hemochromatosis, hypoglycemia and ketosis are perennial threats.^{24, 25}

SUMMARY

Attention is called to a clinical syndrome of abdominal pain in hemochromatosis that has been

mentioned very rarely in the medical literature in the United States.

Three autopsied cases showing no morphologic basis for the abdominal episodes are reported.

Several possible explanations of this syndrome are presented.

I am indebted to Dr Frederic Parker, Jr, for his assistance and valuable suggestions.

MEDICAL PROGRESS

LABORATORY DATA IN CLINICAL MEDICINE UNITS OF MEASURE, COSTS, AND QUANTITATIVE SIGNIFICANCE OF RESULTS*

THOMAS HALE HAM, M D †

BOSTON

THE potential number and cost of laboratory examinations in clinical medicine are enormous. Accordingly, it is a considerable responsibility for the physician to choose wisely the laboratory procedures that are to be performed. Certain

systems of the body for detecting the presence of disease. These procedures include the determination of the hematocrit (or hemoglobin), white-cell count and differential white-cell count, analysis of urine, inspection of the stool, examination for

TABLE 1 Selected Units of Measure from the Metric System, and Relations among Them

Prefixes	UNIT	ABBREVIATION
deci- one-tenth $1/10$ 0.1 10^{-1}		(d)

Units of mass		
1 kilogram (kg)	=	1,000 grams (gm)
1 gram (gm)	=	1,000 milligrams (mg)
1 milligram (mg) = 10^{-3} gm	=	1,000 micrograms (μ g)
1 microgram (μ g)† = 10^{-6} gm	=	1,000,000 micromicrograms ($\mu\mu$ g)†
1 micromicrogram ($\mu\mu$ g)† = 10^{-12} gm		
Units of concentration		
1 mole per liter (M/L) = M_m gm in 1 L (see footnote§)		
1 millimole per liter (mM/L) = $1/1000$ M/L = 10^{-3} M/L		
1 equivalent per liter (eq/L) = M_a gm/valence in 1 L = 10^{-3} eq/L (see footnote§ and Table 2)		
1 milliequivalent per liter (meq/L) = $1/1000$ equivalent per liter = 10^{-3} eq/L		
1 gram per liter (gm/L) = 1,000 milligrams per liter (mg/L)		
1 milligram per liter (mg/L) = 10^{-3} gm/L = 1,000 micrograms per liter (μ g/L)		
1 microgram per liter (μ g/L) = 10^{-6} gm/L = 1,000,000 micromicrograms per liter ($\mu\mu$ g/L)		
1 micromicrogram per liter ($\mu\mu$ g/L) = 10^{-12} gm/L		

* μ is the Greek letter mu. When used alone it means 1 micron; when used as a prefix it means micro-

†Note that some of these relations are only approximate; these are indicated by the sign \approx . True equality is indicated by the sign =. Note that 1 liter is exactly equal to 1000 ml but not exactly equal to 1000 cm³ (see text). The abbreviation cm³ replaces cc.

‡The terms gamma (γ) for microgram and gamma gamma ($\gamma\gamma$) for micromicrogram, have been used but are not recommended since they add confusion and offer no advantage over the standard nomenclature in which μ (mu) indicates one millionth of a meter (micron), μ g indicates one microgram (millionth of a gram) and $\mu\mu$ g indicates one micromicrogram (one million millionth of a gram).

§Note that molecular weight M_m and atomic weight M_a are both pure numbers; see Table 2 for examples using the atomic weight of electrolytes. In physical chemistry molal solutions are used; a molal solution contains 1 gram molecular weight (M_m gm) of solute dissolved in 1000 gm (not ml) of solvent. Thus a 0.2 molal solution contains 0.2 M_m gm of solute per 1000 gm of solvent.

tests have become "routine" because they have proved to give basic information rapidly and inexpensively in the screening of a large number of

occult blood and serologic test for syphilis. As will be discussed in a separate communication, the red-cell count is not recommended as a routine screening procedure.

The choice of laboratory examinations is usually based on symptoms, signs or laboratory data that

*Adapted from *A Syllabus of Laboratory Examinations in Clinical Diagnosis* (in press) by permission of the Harvard University Press.
 †Assistant professor of medicine, Harvard Medical School; associate director, Thorndike Memorial Laboratory; and junior visiting physician, Boston City Hospital.

indicate a presumptive value for the performance of a particular test or group of tests. The use of each laboratory test is based on a knowledge, first, of the clinical indication for performing the test, the nature of the test and the diagnostic significance of the results. Three particular aspects of laboratory examinations are considered in the material presented below — namely, certain units of measure of clinical data, the cost to the patient and the degree of accuracy that is required of a laboratory

indicates a reciprocal, $10^{-3} = 1/10^3 = 1/1000 = 0.001$, $2.65 \times 10^{-6} = 2.65 \times 0.000001 = 0.00000265$. The red-cell count in millions per cubic millimeter may be expressed, for example, as $5.34 \times 10^6/\text{mm}^3$, the white-cell count in thousands per cubic millimeter may be expressed, for example, as $8.23 \times 10^3/\text{mm}^3$ (see Table 6).

Expression of the concentration of *electrolytes* of plasma, serum and extracellular fluids has caused confusion. Ions are usually expressed in terms of

TABLE 2 Normal Values for Electrolytes of Human Serum and Plasma Expressed in Milligrams per 100 ml and Converted to Milliequivalents per Liter as Modified from Gamble[†]

Ion	Normal Values*	Atomic Weight	Valence	Conversion of Concentration C in mg/100 ml to meq/L		Normal Value
	(mg/100 ml)			M_a	V	
Cations						
Na ⁺	313-335	23	1	($C \times 10/23$)	$\times 1 = 0.435$	136-145
K ⁺	14-19	39	1	($C \times 10/39$)	$\times 1 = 0.257$	3.5-5.0
Ca ⁺⁺	9.0-10.5	40	2	($C \times 10/40$)	$\times 2 = 0.5$	4.5-5.3

SO ₄ ⁼ (mgS)	1.6-2.4	31	2	($C \times 10/32$)	$\times 2 = 0.625$	1.0-1.5
Protein (gm/100 ml)	6.5-8.0				2.45‡	16-19
Total						145-157

*Normal values for blood plasma and serum.[‡]

†1 millimole per liter (or 1 milliequivalent per liter) of CO₂ under standard conditions (760 mm-of mercury and 0°C) occupies 22.26 ml or 1 milliequivalent per 100 ml occupies 2.22 ml. Therefore the content (volume) of CO₂ in milliliters per 100 ml of serum (CO₂/volume per cent) when divided by 2.22 gives CO₂ in milliequivalents per liter.

‡As stated by Gamble, the valence of HPO₄ is taken as 1.8 because at the normal pH of extracellular fluid 20 per cent of the concentration of this radical carries 1 equivalent of base (BH₂PO₄) and 80 per cent 2 equivalents (B₂HPO₄). B representing univalent base. Base equivalence per unit of (HPO₄) is therefore 0.2 — (0.8 × 2) = 1.8. The double valency sign is thus small extent inaccurate.

§Derived by titration of the base that is bound by proteins of normal serum at pH 7.35.

procedure so that the results may be significant in establishing an aspect of the diagnosis or treatment.

CERTAIN UNITS OF MEASURE (METRIC SYSTEM)

The physician is called upon to interpret data expressed in units of measure that vary greatly in magnitude. Thus, a patient weighing 70 kg may have a blood volume of 5 liters, a nonprotein nitrogen of 20 mg per 100 milliliters of blood, a blood sodium of 140 milliequivalents per liter, a serum iodine (protein bound) of 4 micrograms per 100 milliliters and a mean corpuscular hemoglobin (for the red cells) of 30 micromicrograms. The shift from micromicrograms to kilograms or from milliequivalents per liter to milligrams per 100 milliliters frequently results in confusion. In Table 1, the usual units of measure in the metric system are arranged in descending order of magnitude, with their abbreviations* and equivalents.

The writing of large or small numbers is facilitated by the use of powers of ten. Thus, 1,000,000 = 10⁶, 1034 = 1.034 × 10³. A negative exponent in-

their chemical equivalence, by the statement of their concentration in milliequivalents per liter, rather than in milligrams or grams per 100 ml. As shown in Tables 1 and 2, the conversion to milliequivalents per liter, for the individual ions, is given by the formula

$$\text{Concentration (meq/L)} = \frac{\text{Concentration (mg/100 ml)} \times 10}{M_a} \times V,$$

where V is the valence and M_a is the atomic weight. The normal values and the formulas for conversion to milliequivalents per liter are shown in Table 2.

It may be remarked that the *unit of volume* used in chemical and biologic work is the *liter*, which is the volume of 1 kg of pure water at the temperature of maximum density, 4°C, and under a pressure equivalent to 760 mm of mercury. It was intended by the constructors of the metric system that the kilogram should be the mass of 1 cubic decimeter (10⁻³ m³) of pure water under these conditions of temperature and pressure, but later, more accurate measurements showed that they had made an error, and the kilogram is now taken as the mass of the international prototype kilogram — a block of metal kept at the International Bureau of Weights

*It will be noted that periods and other punctuations are not used after any abbreviation following the practice of the *Handbook of Chemistry and Physics*. Thirtieth edition. Cleveland: Chemical Rubber Publishing Co., 1948. Pp. 2637-2649. Also the abbreviation of gram or grams is taken as (gm) rather than (gms); similarly milligram or milligrams is abbreviated (mg) rather than (mgm) or (mgms).

and Measures near Paris, it is equal to the mass of $0.001000027 \text{ m}^3 (= 1.000027 \text{ dm}^3)$ of water. Consequently, $1 \text{ ml} = 1.000027 \text{ cm}^3$, but the mass of 1 ml of pure water under the conditions specified is exactly 1 gm . For these reasons the milliliter (ml) is substituted for the more familiar cubic centimeter (cm^3)* as a unit of volume.

For convenience and clarity in expression, units that avoid the use of large numbers or large fractions are chosen when possible. For example, a patient's weight of $70,000 \text{ gm}$ is expressed as 70 kg , a dosage of vitamin B_{12} is more conveniently expressed as $15 \mu\text{g}$ (micrograms) than 0.015 mg or 0.000015 gm or $15 \times 10^{-6} \text{ gm}$, a concentration of potassium in the serum is expressed as 5 milliequivalents per liter (meq/L) rather than 0.005 equivalent per liter (eq/L). The expression "milligrams per cent (mg %)" has caused confusion since, literally, it means the number of milligrams per 100 parts—that is, per 100 mg—and not per 100 cm^3 or per 100 ml, as is usually implied. Accordingly, the expression "milligrams per cent" should be abandoned, and units that are determinate should be used, such as mg/100 ml or mg/L. Thus, the concentration of nonprotein nitrogen in whole blood is expressed as $30 \text{ mg}/100 \text{ ml}$, rather than $0.03 \text{ gm}/100 \text{ ml}$ and not as 30 mg \% .

CURRENT COST OF LABORATORY EXAMINATIONS AND CERTAIN LABORATORY APPARATUS

Unfortunately, laboratory examinations cost money because of the time, skill, reagents, apparatus, and building space required for their proper performance. The increasing number and cost of laboratory procedures required for proper diagnosis and treatment presents a significant economic problem in the care of the patient. There is no doubt that well controlled laboratory examinations are essential, but because they are expensive, they should be ordered with care, done with proper accuracy and interpreted critically. Laboratory examinations are obviously subject to abuses. It may be improper for a patient to pay for extra laboratory examinations that are performed primarily for teaching or research purposes. A more serious error may result from the failure to perform the proper kind or number of tests because of cost to the patient. It is probably essential that the patient be instructed in the need, cost and value of laboratory examinations in his particular case just as he is informed of the need, cost, and value of treatment with an antibiotic or by an operative procedure.

No figures are available on the true costs of laboratory procedures. In place of a cost analysis, the current charges made for certain laboratory tests in different parts of the country are listed in Table 3. At one hospital (No 3 in Table 3) for private patients a flat laboratory fee is charged to each patient to cover routine laboratory work.

*The cubic centimeter—as with other volumes expressed as the cube is abbreviated as (cm^3) rather than the more familiar (cc).

required of all who are admitted. Since the routine varies on different services, the fees charged are as follows: medical patients, \$9.00, surgical patients, \$6.00, obstetric patients, \$4.00. The charges cover blood counts, urinalysis and certain other procedures. Other tests are charged for separately (see column 3, Table 3). All charges are based on a unit system in which each unit is valued at \$0.50,

QUANTITATIVE EVALUATION OF DATA

With the enormous increase in the number of laboratory examinations that can be made, the physician is called upon continuously to evaluate data in a scientific manner—that is, to know the limits of significance of the results quantitatively and clinically. Quite properly, the physician wishes to obtain a maximum of reliable information on which to base a diagnosis, and to obtain it at minimum cost in minimum time and as simply as possible. Accordingly, there will always be a high priority in clinical medicine for the development of *screening examinations* that will indicate the presence or absence of disease in a rapid, reliable and inexpensive manner. The data required may be qualitative, semiquantitative or, in certain instances, precisely quantitative to be of proper use to the physician in diagnosis and treatment. Again, the physician balances the potential value of a test against its cost, but gives first priority to the clinical indication for the procedure.

In general, costs rise with the degree of accuracy required, since precision usually requires more time of highly skilled personnel* and more equipment than qualitative or semiquantitative examinations. Accordingly, the physician will be alert to know the degree of accuracy required and to interpret data with a full knowledge of their limitations in specificity and limits of error. For example, the determination of plasma fibrinogen, serum albumin and serum globulin requires skill in the use of the Kjeldahl method of nitrogen analysis, these determinations inevitably are expensive. If the procedures are done by unskilled workers, the data are erroneous, not reproducible and so misleading clinically as to be useless and treacherous (see Fig 1 for serum albumin). Accordingly, certain screening examinations for plasma proteins that are rapid, inexpensive and semiquantitative have an important place as diagnostic procedures. For example, if the total protein is normal as measured by the copper sulfate method, if the serum globulins are normal as indicated by the formol-gel reaction and if the plasma fibrinogen and serum globulins are normal as indicated by the sedimentation rate, plasma protein fractions may be considered normal, and its quantitative determination is not essential for diagnosis.

It is emphasized, immediately, that it may be as fallacious and wasteful to use a refined quantitative procedure when qualitative results suffice as it is to attempt the evaluation of data of qualitative significance when precise information is necessary. Accordingly, a knowledge of the limits of accuracy of the data is an integral part of their diagnostic

*Fortunately, there are occasional exceptions. For example, the hematocrit can be determined with remarkable accuracy and in a short time by a trained high school girl equipped with a centrifuge and a dozen Wintrobe tubes. This easy precision results from the admirable features of the method itself. Conversely the red-cell count as a method has an inherent error of chance distribution of cells that requires long labor and great care to overcome (see Table 6).

evaluation. There is no place in medicine for blind faith in a written figure on a patient's chart. Listed below are examples of the wide span of the limits of accuracy of data as applied to diagnosis and treatment.

Qualitative Determinations

An unrefined, and possibly nonspecific, qualitative procedure is frequently of great *value* as a screening procedure or as a true diagnostic method. Thus, the presence of gross blood in urine, feces, vomitus or sputum may require only visual observation for detection, and certainly does not require refined quantitative evaluation to be of important diagnostic value. Similarly, if a patient's vomitus produces a bright-red color with the pH indicator, Töpfer's reagent, this is first-class evidence for the presence of free hydrochloric acid and would immediately exclude a diagnosis of classic Addisonian pernicious anemia. If a patient bleeds indefinitely after an ordinary capillary puncture for the collection of blood, this observation is as eloquent data as may be obtained from a test performed especially for measuring the bleeding time. If the urine becomes solidified when boiled with acetic acid, this test alone requires a presumptive diagnosis of nephrosis. If the hematocrit tube shows a layer of white cells that is 10 mm high, the presumptive diagnosis is leukemia until proved otherwise. If a patient enters the hospital with manifest history and signs of dehydration, the observation that the specific gravity of the urine sample is only 1.010 suggests low concentrating power and abnormal renal function. The passage of a stone into urine or stool is a reliable qualitative datum.

However, qualitative determinations have inevitable *limitations* that require full recognition. For example, the observation of blood in the vomitus, without further information concerning the patient, may not indicate whether the bleeding is of minor nature or of a magnitude that threatens the life of the patient. The passage of a stone in the urine does not in itself indicate whether the patient has such an abnormality as a parathyroid tumor, excessive ingestion of alkali or a congenital defect in the metabolism of cystine.

Semiquantitative Determinations

Data of semiquantitative accuracy are frequently as *valuable* as more refined information. This is evidenced by the enormous number of tests, reported in terms of degree of positivity, and expressed as "positive or negative" or positive in terms of "+ to 4+" For example, in a patient with known diabetes, a "brick red" (4+) test with Benedict's qualitative sugar reagent is reliable semiquantitative information, as is a 4+ reaction for acetone bodies. There may be no requirement, in the proper handling of diabetic coma, to determine, in a more quantitative manner, the sugar and acetone bodies in the

of the future will demand information on the limits of significance of the results before he evaluates data in relation to the patient

Statistical Analysis of Certain Data Obtained from Laboratory Examinations of Blood

No attempt is made in this paper to consider statistical methods in general, which are adequately described elsewhere.^{5,11} The discussion here is limited to certain examples of evaluating, by statistical methods, the determinations obtained by about 20 different observers, examining samples of a single specimen of venous blood and using the procedures listed below. Such an exercise can be used to demonstrate the limits of significance of data obtained by different methods and to show improvement in the accuracy of observations resulting from training. The data can then be entered for analysis on a blank form, a portion of which is shown in Table 6. The results shown are typical data obtained by students in training who have already developed considerable proficiency.

Red-cell count The red-cell count is performed in two ways. In the first of these two red-cell

variation, SD , or σ (small sigma). The standard deviation is calculated as follows, using the expressions commonly employed in statistical methods.

The arithmetic average, or mean, M is calculated by obtaining the sum Σ (capital sigma) of the

TABLE 5 Factors Contributing to Technical Inaccuracies and Other Unsatisfactory Conditions in Clinical Laboratories *

FACTOR	No. of Times Listed
Poorly trained technicians	82
Inadequate number of technicians	80
Lack of understanding between pathologist and staff	64
Poor equipment	63
Insufficient floor space	57
Miscellaneous factors (inadequate orderly service, insufficient secretarial service and so forth)	39

*Based on data of Bell and Sunderman.⁴

total number N of observations, each observation being designated by the letter X . Thus,

$$\text{Arithmetic Average or Mean, } M = \frac{\Sigma X}{N}$$

The deviation d of each observation from the mean is calculated by subtraction of the mean from

TABLE 6 Results Obtained by Different Medical Students after Considerable Training in the Examination of Samples of the Same Blood Specimen from a Patient with Cooley's Anemia *

DETERMINATION	NUMBER OF OBSERVATIONS	MAXIMUM	MINIMUM	MEAN (AVERAGE)	TWO STANDARD DEVIATIONS (2 SIGMA)†	TWO COEFFICIENTS OF VARIATION %
Hematocrit (percentage)	10	25.0	23.5	24.1	± 0.84	± 3.4
Hemoglobin (gm/100 ml)						
Photoelectric-cell colorimeter (Evelyn)	9	8.3	7.8	8.0	± 0.36	± 4.5
Spencer hemoglobinometer	17	9.1	8.0	8.7	± 0.78	± 9.0
Sahlb	17	9.7	7.3	8.9	± 1.2	± 14.0
Haden-Hauser	17	8.7	7.5	8.2	± 0.8	± 10.0
Tallqvist	17	9.4	6.5	7.8	± 1.6	± 21.0
Counts of formed elements of blood:						
R. B. C. ($10^6/\text{mm}^3$)						
(2 pipettes, 2 chambers)	20	2.5	2.0	2.2	± 0.36	± 16.0
(1 pipette, 2 chambers)	18	2.4	1.7	2.1	± 0.28	± 13.0
W. B. C. ($10^3/\text{mm}^3$)	18	11.6	7.55	9.1	± 1.83	± 20.0
Reticulocytes wet method (per cent)	19	6.2	2.2	4.0		

*The limits of significance (two coefficients of variations) are representative of the methods themselves and indicate what may be obtained from any laboratory. The small error of the hematocrit and the hemoglobin determined by the photo-electric-cell colorimeter (Evelyn) should be especially noted.

†Units are those of the observations.

pipettes are filled, each being used to fill one counting chamber of a hemacytometer, 400 to 600 cells being counted in each chamber. The results of counts in the two chambers are averaged. Secondly, one red-cell pipette is filled and used to fill both counting chambers of a hemacytometer, the rest of the procedure being carried out as above.

Determination of hemoglobin Five methods are used: the photoelectric-cell colorimeter (Evelyn), Spencer hemoglobinometer (American Optical Company), Sahlb, Haden-Hauser and Tallqvist.

Hematocrit The Wintrobe method is used.

Numerical Expression of the Degree of Deviation of Data, Calculation of the Standard Deviation

It is more convenient to express numerically, rather than graphically, the degree of variation of data, expressing the results as the standard de-

it, $d = X - M$, d may be either positive or negative. The deviation of each observed value is then squared, to give d^2 , and the sum Σd^2 of all the squares is obtained. The mean of the sum of the squares of the deviations $\Sigma d^2/N$ is employed in the finding of σ when N is large, but when the number of observations is small, as in the examples used here, the sum of the squares of the deviation is better divided by $N-1$ (see Fisher⁷). The standard deviation is calculated by determination of the square root of $\Sigma d^2/(N-1)$ — that is,

$$\sigma = \sqrt{\Sigma d^2/(N-1)}$$

An example of the calculation from data for eleven red-cell counts is shown in Table 7.

Interpretation Many biologic measurements tend to follow the so-called *normal distribution*, in which 95 per cent of the observed values fall within the

urine If a spinal tap shows pus cells and a few gram-negative intracellular diplococci, this is presumptive evidence for treatment of the patient for meningococcal meningitis before the bacteriologic examinations have been reported, concerning the fermentation of sugars and the immunologic classifications of the organism If the patient has clinically manifest infectious mononucleosis, the demonstration of 4+ heterophil antibodies in the serum is qualitative and semiquantitative information that has high presumptive value in establishing the diagnosis, treatment of the serum with guinea-pig kidney and the demonstration of nonadsorption of the heterophil antibodies is a further qualitative refinement of confirmatory value In a patient suspected to have liver disease, the finding in the urine of 4+ bile and 4+ color reaction with Ehrlich's aldehyde reagent may be as meaningful in diagnosis as the extraction, qualitative identification and quantitative determination of bilirubin and urobilinogen

The *limitations* of semiquantitative data require as careful recognition as the potential value of such data The greatest abuse in the evaluation of data is the interpretation of semiquantitative results as though they were quantitatively accurate within narrow limits For example, the red-cell count, in unskilled hands, frequently has a limit of significance of ± 20 per cent * The determination of the mean corpuscular volume, therefore, has an error of at least the same order of magnitude However, clinicians may accept the reported mean corpuscular volume at face value in characterizing the size of the red cells Also, there are frequent errors in judgment concerning the interpretation of results of the determination of hemoglobin In this instance, many clinical methods are semiquantitative, as employed, and the reproducibility of results varies within the limits of ± 15 per cent * A physician may report "clinical improvement," using such a method, if two consecutive determinations show a so-called "increase" of 5 per cent, obviously, such a "change" in hemoglobin has no quantitative significance whatsoever

Certain examinations depend upon the *preservation* of such biologic substances as casts or urobilinogen in the urine, bacteria in culture mediums and fixation of biopsy material Semiquantitative determinations made on poorly preserved biologic specimens have inherent errors of significant magnitude that vitiate the results, waste the time of the examiner and may seriously influence diagnosis and treatment of the patient

Quantitative Determinations

The continual addition of quantitative determinations, having known limits of significance, is evidence of the increasing applications of the scientific method in medicine for establishment

of diagnosis and treatment In the field of biochemistry, the clinical *value* of such quantitative determinations is manifest—for example, the measurements of blood sugar, urea, uric acid, calcium and other substances In the biologic field, the determination of hemoglobin by the photoelectric-cell colorimeter and the determination of the hematocrit have made possible results that are reproducible within limits of ± 5 per cent.†

The *limitations* of quantitative determinations in medicine result largely from a failure to appreciate the limits of significance of the particular method, in the hands of the particular examiner, and as determined on a particular sample For example, Belk and Sunderman⁴ sent carefully prepared duplicate samples of known solutions to 59 different laboratories in Pennsylvania for quantitative determinations The range of the results is summarized in Fig 1 It is immediately apparent that many results were grossly wrong, would mislead the physician in establishing a diagnosis and might seriously affect the treatment and, therefore, the life of the patient Belk and Sunderman received opinions from 95 pathologists concerning the causes of unsatisfactory results, these are summarized in Table 5

Sources of error in quantitative determinations A list of sources of error in quantitative determinations in medicine would include at least the following

Objective errors (beyond the control of the examiner)

Sampling error in obtaining a representative sample and in stability, such as preservation, of the biologic specimen

Method errors of measurement, of instruments of assay (specificity, reproducibility)

Subjective errors (within the control of the examiner)

Technical mistakes errors of technical nature as related to quantitative measurement and proper control of the method

Definition of the limits of quantitative significance of data From the above discussion, it is apparent that a qualitative determination may have significance in diagnosis within wide limits of variation of the data The very observation that blood is present in vomitus is a *qualitative datum* that determines the *presence or absence* of a substance The crude observation that the vomitus contains a large, moderate or small amount of blood is a *semiquantitative datum* that has value even though the absolute number of milligrams of hemoglobin in the sample can be given only within wide limits In a quantitative determination, it is necessary to define the significance of the final result if it is to be interpreted properly This is most readily done by one of several statistical methods The physician

*Two coefficients of variation

†Two coefficients of variation

of the future will demand information on the limits of significance of the results before he evaluates data in relation to the patient

Statistical Analysis of Certain Data Obtained from Laboratory Examinations of Blood

No attempt is made in this paper to consider statistical methods in general, which are adequately described elsewhere.⁵⁻¹¹ The discussion here is limited to certain examples of evaluating, by statistical methods, the determinations obtained by about 20 different observers, examining samples of a single specimen of venous blood and using the procedures listed below. Such an exercise can be used to demonstrate the limits of significance of data obtained by different methods and to show improvement in the accuracy of observations resulting from training. The data can then be entered for analysis on a blank form, a portion of which is shown in Table 6. The results shown are typical data obtained by students in training who have already developed considerable proficiency.

Red-cell count The red-cell count is performed in two ways. In the first of these two red-cell

variation, S D, or σ (small sigma). The standard deviation is calculated as follows, using the expressions commonly employed in statistical methods.

The arithmetic average, or mean, M is calculated by obtaining the sum Σ (capital sigma) of the

TABLE 5 *Factors Contributing to Technical Inaccuracies and Other Unsatisfactory Conditions in Clinical Laboratories**

FACTOR	No. of TIMES LISTED
Poorly trained technicians	82

*The limits of significance (two coefficients of variations) are representative of the methods themselves and indicate what may be obtained from any laboratory. The small error of the hematocrit and the hemoglobin determined by the photo-electric-cell colorimeter (Evelyn) should be especially noted.

†Units are those of the observations.

pipettes are filled, each being used to fill one counting chamber of a hemacytometer, 400 to 600 cells being counted in each chamber. The results of counts in the two chambers are averaged. Secondly, one red-cell pipette is filled and used to fill both counting chambers of a hemacytometer, the rest of the procedure being carried out as above.

Determination of hemoglobin Five methods are used: the photoelectric-cell colorimeter (Evelyn), Spencer hemoglobinometer (American Optical Company), Sahli, Haden-Hauser and Tallqvist. **Hematocrit** The Wintrobe method is used.

Numerical Expression of the Degree of Deviation of Data Calculation of the Standard Deviation

It is more convenient to express numerically, rather than graphically, the degree of variation of data, expressing the results as the standard de-

it, $d = X - M$, d may be either positive or negative. The deviation of each observed value is then squared, to give d^2 , and the sum Σd^2 of all the squares is obtained. The mean of the sum of the squares of the deviations $\Sigma d^2/N$ is employed in the finding of σ when N is large, but when the number of observations is small, as in the examples used here, the sum of the squares of the deviation is better divided by $N-1$ (see Fisher⁷). The standard deviation is calculated by determination of the square root of $\Sigma d^2/(N-1)$ — that is,

$$\sigma = \sqrt{\Sigma d^2/(N-1)}$$

An example of the calculation from data for eleven red-cell counts is shown in Table 7.

Interpretation Many biologic measurements tend to follow the so-called *normal distribution*, in which 95 per cent of the observed values fall within the

urine If a spinal tap shows pus cells and a few gram-negative intracellular diplococci, this is presumptive evidence for treatment of the patient for meningococcal meningitis before the bacteriologic examinations have been reported, concerning the fermentation of sugars and the immunologic classifications of the organism If the patient has clinically manifest infectious mononucleosis, the demonstration of 4+ heterophil antibodies in the serum is qualitative and semiquantitative information that has high presumptive value in establishing the diagnosis, treatment of the serum with guinea-pig kidney and the demonstration of nonadsorption of the heterophil antibodies is a further qualitative refinement of confirmatory value In a patient suspected to have liver disease, the finding in the urine of 4+ bile and 4+ color reaction with Ehrlich's aldehyde reagent may be as meaningful in diagnosis as the extraction, qualitative identification and quantitative determination of bilirubin and urobilinogen

The *limitations* of semiquantitative data require as careful recognition as the potential value of such data The greatest abuse in the evaluation of data is the interpretation of semiquantitative results as though they were quantitatively accurate within narrow limits For example, the red-cell count, in unskilled hands, frequently has a limit of significance of ± 20 per cent * The determination of the mean corpuscular volume, therefore, has an error of at least the same order of magnitude However, clinicians may accept the reported mean corpuscular volume at face value in characterizing the size of the red cells Also, there are frequent errors in judgment concerning the interpretation of results of the determination of hemoglobin In this instance, many clinical methods are semiquantitative, as employed, and the reproducibility of results varies within the limits of ± 15 per cent * A physician may report "clinical improvement," using such a method, if two consecutive determinations show a so-called "increase" of 5 per cent, obviously, such a "change" in hemoglobin has no quantitative significance whatsoever

Certain examinations depend upon the *preservation* of such biologic substances as casts or urobilinogen in the urine, bacteria in culture mediums and fixation of biopsy material Semiquantitative determinations made on poorly preserved biologic specimens have inherent errors of significant magnitude that vitiate the results, waste the time of the examiner and may seriously influence diagnosis and treatment of the patient

Quantitative Determinations

The continual addition of quantitative determinations, having known limits of significance, is evidence of the increasing applications of the scientific method in medicine for establishment

of diagnosis and treatment In the field of biochemistry, the clinical *value* of such quantitative determinations is manifest—for example, the measurements of blood sugar, urea, uric acid, calcium and other substances In the biologic field, the determination of hemoglobin by the photoelectric cell colorimeter and the determination of the hematocrit have made possible results that are reproducible within limits of ± 5 per cent.†

The *limitations* of quantitative determinations in medicine result largely from a failure to appreciate the limits of significance of the particular method, in the hands of the particular examiner, and as determined on a particular sample For example, Belk and Sunderman⁴ sent carefully prepared duplicate samples of known solutions to 59 different laboratories in Pennsylvania for quantitative determinations The range of the results is summarized in Fig 1 It is immediately apparent that many results were grossly wrong, would mislead the physician in establishing a diagnosis and might seriously affect the treatment and, therefore, the life of the patient Belk and Sunderman received opinions from 95 pathologists concerning the causes of unsatisfactory results, these are summarized in Table 5

Sources of error in quantitative determinations A list of sources of error in quantitative determinations in medicine would include at least the following

Objective errors (beyond the control of the examiner)

Sampling error in obtaining a representative sample and in stability, such as preservation, of the biologic specimen

Method errors of measurement, of instruments of assay (specificity, reproducibility)

Subjective errors (within the control of the examiner)

Technical mistakes errors of technical nature as related to quantitative measurement and proper control of the method

Definition of the limits of quantitative significance of data From the above discussion, it is apparent that a qualitative determination may have significance in diagnosis within wide limits of variation of the data The very observation that blood is present in vomitus is a *qualitative datum* that determines the *presence or absence* of a substance The crude observation that the vomitus contains a large, moderate or small amount of blood is a *semiquantitative datum* that has value even though the absolute number of milligrams of hemoglobin in the sample can be given only within wide limits In a quantitative determination, it is necessary to define the significance of the final result if it is to be interpreted properly This is most readily done by one of several statistical methods The physician

BENJAMIN CASTLEMAN, M D, *Associate Editor*

EDITH E PARRIS, *Assistant Editor*

CASE 35391

PRESENTATION OF CASE

A forty-two-year-old handy man was admitted to the hospital because of anorexia and diarrhea.

The patient had been well until eleven years before entry, when he noted progressive enlargement of the lymph nodes of the neck. He was admitted to another hospital where a biopsy of one of the lymph nodes was performed and a subsequent diagnosis of Hodgkin's lymphoma rendered. He received several courses of x-ray therapy for recurrent masses in the neck with good results and was well until two years before the present admission when he was admitted to this hospital because of anorexia, vomiting, nausea and weight loss of 36 pounds of five months' duration.

Physical examination revealed a generalized superficial lymphadenopathy and a moderately enlarged spleen. A repeat biopsy of the axillary lymph nodes confirmed the previous diagnosis of Hodgkin's lymphoma. The patient was considered a "terminal problem" and was given six doses of nitrogen mustard following which he made a striking recovery, became asymptomatic, regained his normal weight and was soon back at work. Eight months later, however, because of recurrent symptoms and weight loss, he was readmitted and given five doses of nitrogen mustard following which he again responded dramatically with subsequent return to work. Four months before the present admission he was seen in the Tumor Clinic, where he complained of another recurrence of symptoms and at which time palpable inguinal lymph nodes were found. The patient was given x-ray therapy with diminution in the size of the masses in these areas. Six weeks before admission he returned to the Tumor Clinic, still complaining of nausea, weakness and weight loss. At this time physical examination failed to show any lymphadenopathy. One week prior to entry he complained of diarrhea of one

month's duration. Stools occurred six to nine times daily, were watery brown without mucus or blood and were accompanied by severe cramps and tenesmus. There had been a 20-pound weight loss but no vomiting and only slight nausea. General malaise and weakness had been progressive.

Examination showed an emaciated, somewhat pale middle-aged man in no acute distress. There was slight to moderate generalized lymphadenopathy. The heart was not enlarged, the rhythm was regular, and the aortic second sound was greater than the pulmonic. A Grade I systolic murmur was present at the apex. The abdomen was normal except for considerable voluntary spasm. There was ++ pitting edema of the ankles.

The blood pressure was 100 systolic, 65 diastolic. The temperature, pulse and respirations were normal.

The urine was yellowish brown and gave a ++++ test for albumin. The sediment contained rare red cells and 5 to 10 white cells per high-power field and many granular casts. Examination of the blood disclosed a red-cell count of 3,300,000, with a hemoglobin of 13.3 gm, and a white-cell count of 11,100, with 89 per cent neutrophils. A smear showed a normocytic, normochromic anemia. A stool was guaiac negative.

Because of the patient's previous good response to nitrogen mustard therapy it was decided to treat him again in this way, and he was subsequently given five doses of 65 mg of nitrogen mustard intravenously over a five-day period. After two days in the hospital, apparently in response to antispasmodic treatment, diarrhea decreased to one or two watery movements a day. The appetite remained poor, however, and symptomatically there was little change. A roentgenogram of the chest showed clear lung fields and no definite hilar-lymph-node enlargement. A barium enema was negative. Agglutination tests for brucella and organisms of the typhoid-para-typhoid group were negative.

On the fifth hospital day some presacral edema was noted, and there was a suggestion of a small amount of ascites.

On the sixth hospital day laboratory examination showed a serum protein of 3.54 gm per 100 cc, with an albumin of 1.79 gm, and a globulin of 1.75 gm per 100 cc. (albumin-globulin ratio of 1). The nonprotein nitrogen was 62 mg per 100 cc, the sodium 126.5 milliequiv per liter, the carbon dioxide 28 milliequiv per liter, the prothrombin time 29 (normal 15 seconds), calcium 5.3 mg per 100 cc, phosphorus 7.3 mg per 100 cc, and phosphatase 61 units per 100 cc. A Congo-red test showed a small amount of dye in the five-minute specimen and almost none in the sixty-minute specimen. On the same day, during an attempted gastrointestinal series, the patient became very weak and upon return to the ward was found to be in shock, with a blood pressure of 60 systolic, 0

numerical limits $M \pm 2\sigma$ —that is, between two standard deviations above and below the mean. The chance that a single observation will fall within these limits is therefore 95 in 100, the chance that it will fall outside these limits is 5 in 100. An observation falling outside these limits is thus considered abnormal, although the chance is 0.05 that it is not.

Numerical Expression of the Degree of Variation of Data, Calculation of the Coefficient of Variation

As the definition of σ shows, the limits of variation are always expressed in the same units as the

TABLE 7 Example of the Calculation of the Standard Deviation σ from Eleven Determinations of the Red-Cell Count

RED CELL COUNT, λ	DEVIATION FROM MEAN $d [=(X-M)]$	d^2
millions/mm ³	millions/mm ³	
3.6	+0.1	0.01
3.7	+0.2	0.04
3.2	-0.3	0.09
3.5	0.0	0.00
3.6	+0.1	0.01
3.2	-0.3	0.09
3.5	0.0	0.00
3.4	-0.1	0.01
3.6	+0.1	0.01
3.5	0.0	0.00
3.5	0.0	0.00
$\Sigma \lambda = 38.3$		$\Sigma d^2 = 0.26$

$$N = 11$$

$$M = \frac{\Sigma X}{N} = \frac{38.3}{11} = 3.5$$

$$\sigma = \sqrt{\frac{\Sigma d^2}{N-1}} = \sqrt{\frac{0.26}{10}} = \sqrt{0.026} = \pm 0.16 \text{ million/mm}^3$$

quantity measured, thus, for the red-cell count, the units are millions per cubic millimeter, for hemoglobin, grams per 100 ml, and for the hematocrit, per cent. The standard deviations of determinations of red-cell count, hemoglobin and hematocrit cannot be directly compared with one another because the units differ. However, comparison can be made between quantities that have no units. For this purpose there is the *coefficient of variation*, C V, which is defined as the ratio of the standard deviation to the mean, and may be expressed in per cent. Thus, $C V = (\sigma/M) \times 100$ per cent.

From the example in Table 7, where $\sigma = \pm 0.16$ million red cells/mm³, it is found that

$$C V = \frac{\pm 0.16}{3.5} \times 100 = \pm 4.6 \text{ per cent}$$

The interpretation of two coefficients of variation (2 C V) is the same as that of two standard deviations (2 σ), the only difference being the units of expression.

SUMMARY AND RECOMMENDATIONS

The physician himself will recognize the limits of significance of qualitative and semiquantitative determinations. However, he may have no way of knowing and, therefore, *must be informed* of the limits of significance of data obtained by a quantitative determination. Thus, it might be within practical possibility to record clinical data with a statement of the limits of significance, as indicated for certain tests in Table 6, for example, calcium, 10 mg/100 ml (2 C V \pm 5 per cent), red-cell count, 1.8 10^6 /mm³ (2 C V \pm 14 per cent), hemoglobin 12 gm/100 ml (2 C V \pm 15 per cent), total protein, 6.2 gm/100 ml serum (2 C V \pm 10 per cent). An individual laboratory worker can control subjective errors, and can determine and state precisely the objective error of any given method, with much benefit to the accuracy and significance of expensive and important laboratory results.

I am indebted to Mr. Joseph D. Elder, of the Harvard University Press, for contributions on the units of measure, and to Miss Jane Worcester, of the Harvard School of Public Health, and to Dr. Fred H. Allen, of the Children's Hospital, for aiding in the section on quantitative evaluation of data.

In summary, I believe the patient had Hodgkin's disease that involved the intestine, with perforation and peritonitis, and that he had secondary amyloidosis with the chief clinical manifestation of amyloid nephritis with uremia

DR JAMES B TOWNSEND He had some x-ray treatment toward the end in the inguinal region Did he have enough to produce x-ray proctitis?

DR SHORT That is possible I assume that he did not have large doses

DR STANLEY M WYMAN I do not know about that Would you care to see the films, Dr Short?

DR SHORT They were considered normal in the protocol That is why I did not ask for them

DR WYMAN I think there is some information that helps The chest films were taken over a two-year period and show no significant intrinsic disease that I can recognize The patient had a gastrointestinal series when first seen, and there is no evidence of definite intrinsic disease The barium enema done on the last admission is not remarkable except for a poor demonstration of the cecum, which may be due to spasm at the time the films were taken However, I cannot exclude organic disease in that region from these films alone The films taken from the gastrointestinal examination done on this admission are quite striking The first film shows a dilated, apparently fluid-filled stomach and a very markedly dilated duodenal loop The second film, taken two hours later, shows no apparent progress of the barium from its original location in the duodenum At that time several loops of dilated small bowel are seen scattered throughout the abdomen A film taken two days after the gastrointestinal examination shows a very abnormal series of small-bowel loops, which are considerably dilated and still filled with barium from the gastrointestinal series taken two days before apparently There is no gas in the colon, and none in the rectum The x-ray picture represents an obstructive lesion in the lower ileum I do not know how to tie it up with the picture in the cecum

DR BENJAMIN CASTLEMAN What was the date?

DR WYMAN Two days before death

DR SHORT That would be evidence for the possibility of tumor obstructing in that area

DR WYMAN Mechanical obstruction in the loop of ileum or probably a paralytic ileus could look essentially the same

DR SHORT Do you think the absence of air rules out the possibility of perforation?

DR WYMAN I think it is serious evidence against it, but I am not able to recognize a true film of the abdomen, taken in the upright position, to exclude that

Hodgkin's disease.

Uremia

Amyloidosis?

DR SHORT'S DIAGNOSES

Hodgkin's disease, involving intestine, with perforation and peritonitis

Secondary amyloidosis, chiefly involving kidneys

ANATOMICAL DIAGNOSES

Malignant lymphoma, Hodgkin's type, involving lymph nodes only

Amyloidosis of liver, adrenal glands and especially of kidneys and lymph nodes

Amyloid nephrosis (with uremia)

Acute enteritis

PATHOLOGICAL DISCUSSION

DR CASTLEMAN A review of the biopsy of the lymph node removed two years previously showed Hodgkin's disease, of the type that has been described by Jackson and Parker¹ as very early—what they call Hodgkin's paraganuloma In this type the architecture of the nodes is not too markedly distorted, there is no evidence of fibrosis and only a few eosinophils, but the Reed-Sternberg cells are present This microscopical picture would fit in with the long history of Hodgkin's disease that this patient had—thirteen years Jackson and Parker¹ have reported cases in which patients with nodes of this character have lived for as long as twenty-five years and in which the nodes retain their paraganuloma appearance without ever going over into a true Hodgkin's granuloma or the more classic Hodgkin's disease

Autopsy showed large numbers of nodes in the mediastinum and retroperitoneal areas predominantly, as well as in the cervical and axillary regions Some of them were quite large, especially in the abdomen, along the aorta, forming masses reaching 9 cm in length When these were cut, they were quite firm and almost fibrous Grossly it was believed to be Hodgkin's disease Microscopical examination, however, showed that it was practically all amyloid One has to hunt to find any cell that could be called a Reed-Sternberg cell of Hodgkin's disease We sectioned about 20 nodes, and all showed the same picture diffuse replacement by amyloid, with a periphery of cells and an occasional Sternberg cell Going back to the original node removed two years before the final admission, we found no evidence of amyloid, so that we have evidence, I believe, that the amyloid developed within a two-year period Since every node examined at autopsy was involved with amyloid, it would be a little farfetched to think that this particular biopsied node escaped at that time We found no evidence of Hodgkin's disease in the liver, spleen, kidney or intestines There was amyloid disease in the liver, kidney, and adrenal glands, but in no other organ, except the nodes

The kidneys were very big, weighing 800 gm together, which is about two and a half times the

diastolic The pulse was 120 Physical examination at this time did not reveal a cause for the change in the patient's condition, but peristalsis was noted to be absent A roentgenogram of the abdomen was negative for free air Following a transfusion of 1000 cc of blood the blood pressure rose to 98 systolic, 58 diastolic Despite this improvement the patient was still irrational at times The skin was warm and moist, the lungs clear, and the heart rate 98 and regular The abdomen was moderately distended, soft and diffusely tender but without rebound tenderness Peristalsis was absent There was no vomiting On the seventh hospital day the patient appeared toxic but was not in the profound shock of the previous day Early in the day the physical findings were unchanged, but later peristalsis was heard A stool gave a ++ guaiac reaction, and the blood hemoglobin was 11.5 gm Five hundred cubic centimeters of brown, watery fluid was aspirated from the stomach and gave a + guaiac reaction Despite additional blood and supportive therapy the patient's course was progressively downhill On the eighth hospital day he was incontinent and passed foul, yellowish-gray fluid material by rectum Oral fluid intake was limited because of nausea, and intravenous fluid intake was intentionally kept somewhat low in the face of the ankle edema and ascites The systolic blood pressure was 166 The nonprotein nitrogen remained low, and urine output was depressed On the ninth hospital day he was found dead in bed

Whereas urine examinations previous to this admission had been negative, six different examinations during this period of hospitalization gave ++++ tests for albumin, and the sediment contained 4 to 6 white cells and red cells per high-power field All specimens contained numerous hyaline and granular casts The specific gravity ranged from 1.012 to 1.015 The white-cell count, which had been 11,100 on admission, fell progressively to a low of 2200 on the seventh hospital day

DIFFERENTIAL DIAGNOSIS

DR CHARLES L. SHORT The original diagnosis of Hodgkin's disease in this patient was made by biopsy eleven years before his final admission He had an unusually long remission, nine years, following the first course of x-ray therapy It would be of interest to learn from the pathologist whether the original biopsy showed a less malignant type, according to Jackson and Parker's¹ classification, than the second one taken two years before his death The patient was next treated with nitrogen mustard and twice made striking responses, with remissions lasting eight and ten months respectively This case demonstrates the value, at times, of nitrogen mustard treatment

Six weeks before his final admission, a new train of symptoms appeared that seemed to be localized to the gastrointestinal tract in the form of intrac-

table diarrhea The finding of generalized adenopathy on admission points to a recurrence of Hodgkin's disease, but the urinary findings can hardly be explained on that basis The patient's course was rapidly downhill, with the development of edema and ascites and finally uremia The episode on the sixth hospital day suggests intestinal perforation, with peritonitis, probably localized, or the point of perforation sealed off fairly rapidly, since peristalsis reappeared and there were never any frank signs of generalized peritonitis The final discharge of foul fluid from the rectum may have represented perforation and drainage of an abscess by this route

The next question to be decided is whether the patient died of Hodgkin's disease or a complication of this condition, or whether the treatment employed had anything to do with it Perhaps a combination of these three factors was active I think the diagnosis of amyloidosis secondary to Hodgkin's disease can be made with reasonable certainty in this patient in view of the nearly complete disappearance of Congo red from the blood stream A recent paper from the Mayo Clinic² states that in 2 cases out of 30 of secondary amyloidosis the primary lesion was Hodgkin's disease

The blood chemical findings revealed an elevated nonprotein nitrogen, a low serum protein and altered serum calcium and phosphorus values I do not believe it is necessary to bring in the possibility of parathyroid destruction by amyloid or tumor to explain these calcium and phosphorus values In fact, I do not know of any such cases as yet reported Low serum sodium and hypotension suggest Addison's disease, which rarely occurs secondary to amyloidosis or to neoplasm I think there is no way of making the diagnosis without further evidence, although amyloid deposits were probably found in the adrenal cortex at autopsy This is a common site for secondary amyloidosis Deposits were also probably found in the liver but not to the extent of producing any severe dysfunction of this organ The increased prothrombin time may be accounted for by malabsorption due to the intestinal disease

We are left with the diarrhea and probable intestinal perforation to explain Although the small intestine may be involved in amyloidosis to the extent of diarrhea and even a sprue-like syndrome, I have been unable to find any cases going on to actual perforation Nitrogen mustard in at least 2 cases³ has apparently produced ulceration and perforation of the gastrointestinal tract, but this complication must be rare Furthermore, this patient's diarrhea had started before the last administration of the nitrogen mustard Involvement of the intestine is not uncommon in Hodgkin's disease and may lead to ulceration and perforation I would prefer this explanation for the abdominal findings, with the possibility that the perforation was due to destruction of Hodgkin's tissue by the nitrogen mustard

In summary, I believe the patient had Hodgkin's disease that involved the intestine, with perforation and peritonitis, and that he had secondary amyloidosis with the chief clinical manifestation of amyloid nephritis with uremia

DR JAMES B TOWNSEND He had some x-ray treatment toward the end in the inguinal region Did he have enough to produce x-ray proctitis?

DR SHORT That is possible I assume that he did not have large doses

ANATOMICAL DIAGNOSES

Malignant lymphoma, Hodgkin's type, involving lymph nodes only

Amyloidosis of liver, adrenal glands and especially of kidneys and lymph nodes

Amyloid nephrosis (with uremia)

Acute enteritis

PATHOLOGICAL DISCUSSION

DR CASTLEMAN A review of the biopsy of the lymph node removed two years previously showed Hodgkin's disease, of the type that has been described by Jackson and Parker¹ as very early—what they call Hodgkin's paragranuloma In this type the architecture of the nodes is not too markedly distorted, there is no evidence of fibrosis and only a few eosinophils, but the Reed-Sternberg cells are present This microscopical picture would fit in with the long history of Hodgkin's disease that this patient had—thirteen years Jackson and Parker¹ have reported cases in which patients with nodes of this character have lived for as long as twenty-five years and in which the nodes retain their paragranuloma appearance without ever going over into a true Hodgkin's granuloma or the more classic Hodgkin's disease

Autopsy showed large numbers of nodes in the mediastinum and retroperitoneal areas predominantly, as well as in the cervical and axillary regions Some of them were quite large, especially in the abdomen, along the aorta, forming masses reaching 9 cm in length When these were cut, they were quite firm and almost fibrous Grossly it was believed to be Hodgkin's disease Microscopical examination, however, showed that it was practically all amyloid One has to hunt to find any cell that could be called a Reed-Sternberg cell of Hodgkin's disease We sectioned about 20 nodes, and all showed the same picture diffuse replacement by amyloid, with a periphery of cells and an occasional Sternberg cell Going back to the original node removed two years before the final admission, we found no evidence of amyloid, so that we have evidence, I believe, that the amyloid developed within a two-year period Since every node examined at autopsy was involved with amyloid, it would be a little farfetched to think that this particular biopsied node escaped at that time We found no evidence of Hodgkin's disease in the liver, spleen, kidney or intestines There was amyloid disease in the liver, kidney, and adrenal glands, but in no other organ, except the nodes

The kidneys were very big, weighing 800 gm together, which is about two and a half times the

normal weight, and they were very pale and glassy. There was very little evidence of scarring. Practically every glomerulus was involved with amyloid, but rarely was a whole corpuscle completely replaced. The striking finding in this case was in the tubules, which were plugged with casts, and the epithelial cells were swollen and filled with hyaline granules — characteristic of so-called amyloid nephrosis. The intestines, both colon and small bowel, showed scattered areas of hemorrhage, and on microscopical examination there was some cellular infiltration of the submucosa, an acute or subacute process, similar to what we have seen occasionally in uremia. There were, however, no ulcerations in the bowel. Whether this was due to the uremia or uremia in addition to the effect of nitrogen mustard, I do not know. I cannot account for the intestinal obstruction satisfactorily unless it was paralytic ileus as a result of uremia.

DR WYMAN: I was thinking in terms of ileus as a result of vascular accident or uremia possibly to account for the picture.

DR CASTLEMAN: The association of amyloidosis with Hodgkin's disease is not very common. Dr Morgan, of our resident staff, looked up our cases and found that of 60 cases of Hodgkin's disease 5 had amyloidosis. It is interesting that in the series at the Boston City Hospital, reported by Jackson and Parker,¹ there was 1 case very similar to this one in which the amyloid was limited to lymph nodes, replacing them almost completely.

DR JAMES H. CURRENS: Ileus has been described with potassium deficiency.⁵ We have no information here, but it would be interesting to know whether he was losing excess potassium or retaining potassium. Occasionally, these patients, particularly with vomiting, can lose tremendous amounts of potassium, which may result in ileus.

DR CASTLEMAN: What about the level of potassium in uremia?

DR CURRENS: It may be high or low, it is usually high, but occasionally it may be low. Recently, a patient died in this hospital with a nonprotein nitrogen of 150 mg per 100 cc, and a serum potassium of 12 milliequiv per liter (normal, 3.5 to 5.0 milliequiv per liter). It is a possible explanation.

CASE 35392

PRESENTATION OF CASE

First admission. A thirty-nine-year-old housewife entered the hospital complaining of swollen legs.

At the age of fourteen the patient had severe pains in the feet and ankles. A heart murmur was noted, and she was kept in bed for about six months. With clearing of the joint pains she was allowed to resume normal activities but on doing so developed "Saint Vitus dance," described as purposeless twitchings of the hands and arms, which lasted about one and a half years, and then disappeared completely. The patient was well until the age of twenty-four, when, two weeks before the birth of her first child, she developed ankle edema that cleared spontaneously after delivery. She was then free of symptoms until one year prior to admission, when she developed palpitations and exertional dyspnea. Shortly before entry she noted ankle swelling, severe exertional dyspnea and orthopnea requiring three pillows, with almost weekly attacks of paroxysmal nocturnal dyspnea. There was no cough, chest pain, or fever.

Physical examination revealed marked engorgement and pulsation of the neck veins. Many moist rales were present throughout both lung fields. The heart rate was rapid and irregular, with an apical rate of 110 and a radial pulse of 96. There were enlargement of the heart to percussion and an apical systolic thrill. Harsh apical systolic and diastolic murmurs and a blowing diastolic murmur in the aortic area were heard. The liver edge was 5 cm below the costal margin. The ankles and calves showed marked pitting edema.

The temperature was 99.2°F, and the respirations were 24. The blood pressure was 174 systolic, 98 diastolic.

Laboratory studies on the urine showed a specific gravity of 1.018, with a trace of albumin. Blood studies, including the white-cell count, nonprotein nitrogen, carbon dioxide and total protein, were not remarkable. An electrocardiogram demonstrated auricular fibrillation alternating with idioventricular rhythm. X-ray studies of the chest showed a small amount of fluid in the left costophrenic angle and considerable generalized cardiac enlargement.

Following digitalization the patient improved steadily until two and a half weeks had elapsed, and then she suddenly developed severe pain in the right lower chest and hemoptysis. Roentgenograms revealed a large area and several smaller areas of increased density in the right lower lobe. Surgical interruption of both common femoral veins was done, but no clots were found. Improvement was slow but steady, and after three months the patient returned home on a regimen of digitalis, ammonium chloride and weekly injections of mercurhydrin.

Second admission (four months later). The patient did well until approximately four months

after the first admission, when she again developed severe pain in the lower chest for which she was readmitted. Chest x-ray films showed a new area of increased density in the anterior portion of the right lower lobe. Heparin and dicumarol were instituted, and shortly thereafter she became asymptomatic and was discharged two weeks later.

Final admission (one year later) Over the ensuing year the patient enjoyed limited activity and was fairly well until two weeks prior to re-entry. Rather suddenly she became extremely nervous and jittery and developed coarse, involuntary tremor of the hands and feet. She had several, apparently unprovoked, episodes of uncontrollable shrieking and crying and other sudden episodes of confusion, disorientation and memory disturbances. With the onset of these symptoms she noted a diffuse, slightly itchy erythema of the hands, feet and extensor surfaces of the forearms and lower legs. There was no fever, chills, chest pain or hemoptysis, and no evidence of embolic phenomena.

On physical examination the patient lay in bed in no acute discomfort, but there were occasional twitchings of the hands and feet. There was a diffuse, rose-red erythema over the dorsal surfaces of the hands and feet and the extensor surfaces of the legs and forearms, which blanched on pressure. The skin was cool and moist. The neck veins were engorged and pulsating. The lungs were clear except for an area of dullness at the right posterior base. The heart showed no change from previous examinations. The remainder of the examination, including the neurologic examination, was negative except for moderate pitting edema of the ankles.

The temperature was 97°F, the pulse 88, and the respirations 20. The blood pressure was 130 systolic, 90 diastolic.

Examination of the blood revealed a white-cell count of 12,000, with 66 per cent neutrophils, 25 per cent lymphocytes, 6 per cent monocytes, 2 per cent eosinophils and 1 per cent basophils. An electrocardiogram showed a rate of 90. The QRS complex was 0.07, and the T waves were obscured by coarse auricular fibrillations. There was right-axis deviation. Chest x-ray films showed linear scarring in the region of the previous densities in the lung fields and little change in the heart. The sodium was 139.5 milliequiv, and the chloride 102 milliequiv per liter and the nonprotein nitrogen 66 mg per 100 cc.

The erythema had disappeared, and the coarse tremors of the extremities had diminished by the day after admission. Over the next two days, however, the patient's behavior became more bizarre, with almost continuous hysterical crying and thrashing about the bed. Much of the time she seemed entirely out of contact with her surroundings. Despite the marked behavior change, examination showed only cyanosis of the extremities and a dusky, reddish-purple discoloration of the skin.

Her condition rapidly deteriorated, and by the sixth hospital day she was completely unresponsive. The cyanosis had gradually deepened, and she became markedly dyspneic and hyperpneic. The apical pulse was 112, and the radial pulse 52. However, the lungs remained clear. Despite oxygen therapy the cyanosis progressively deepened, and the pulse gradually weakened. The temperature spiked to 105°F, the circulation slowly failed, and she died on the seventh hospital day.

DIFFERENTIAL DIAGNOSIS

DR GORDON S MYER This patient seemed to present no unusual problem until the time of her third and final admission to the hospital. There is a history perfectly consistent with the occurrence of active rheumatic fever and chorea at the age of fourteen, at which time a heart murmur was noted. The onset of rheumatic fever as late in childhood as this and the associated chorea would both favor a relatively good prognosis. This was borne out since she was apparently quite well until the age of thirty-six or thirty-seven years except for one brief episode of ankle edema, which may or may not have represented mild congestive failure toward the end of her pregnancy at twenty-four years of age.

One year prior to her first admission to the hospital the patient went into definite congestive heart failure associated with palpitation, which evidently represented the onset of auricular fibrillation. Such an association between the occurrence of auricular fibrillation and the appearance of heart failure is certainly common in patients with rheumatic heart disease. Physical examination indicated the presence of pulmonary congestion and right-sided failure on the basis of rheumatic heart disease with mitral stenosis and regurgitation and aortic regurgitation and auricular fibrillation and with a rather rapid ventricular rate and a pulse deficit. In addition, a slight hypertension was present and there was some albuminuria. The appearance of a small amount of fluid in the left pleural cavity makes one think of pulmonary embolus even then, since in uncomplicated heart failure the right pleural cavity is most apt to accumulate fluid first. In any case, she later evidenced the classic signs and symptoms of pulmonary emboli, for which femoral-vein ligation was carried out. She was then sent out on routine therapy for control of the congestive failure.

The second admission to the hospital was occasioned by the recurrence of chest pain. When chest x-ray films revealed changes consistent with a new pulmonary infarct she was given anticoagulant therapy. Where did the embolus arise? It may, of course, have come from the common femoral arteries above the point of their ligation or from veins in the pelvis, but a more likely source would be a thrombus in the right auricle.

We now come to what I believe is the central problem. What was the nature of the complication

normal weight, and they were very pale and glassy. There was very little evidence of scarring. Practically every glomerulus was involved with amyloid, but rarely was a whole corpuscle completely replaced. The striking finding in this case was in the tubules, which were plugged with casts, and the epithelial cells were swollen and filled with hyaline granules — characteristic of so-called amyloid nephrosis. The intestines, both colon and small bowel, showed scattered areas of hemorrhage, and on microscopical examination there was some cellular infiltration of the submucosa, an acute or subacute process, similar to what we have seen occasionally in uremia. There were, however, no ulcerations in the bowel. Whether this was due to the uremia or uremia in addition to the effect of nitrogen mustard, I do not know. I cannot account for the intestinal obstruction satisfactorily unless it was paralytic ileus as a result of uremia.

DR WYMAN: I was thinking in terms of ileus as a result of vascular accident or uremia possibly to account for the picture.

DR CASTLEMAN: The association of amyloidosis with Hodgkin's disease is not very common. Dr Morgan, of our resident staff, looked up our cases and found that of 60 cases of Hodgkin's disease 5 had amyloidosis. It is interesting that in the series at the Boston City Hospital, reported by Jackson and Parker,¹ there was 1 case very similar to this one in which the amyloid was limited to lymph nodes, replacing them almost completely.

DR JAMES H. CURRENS: Ileus has been described with potassium deficiency.⁵ We have no information here, but it would be interesting to know whether he was losing excess potassium or retaining potassium. Occasionally, these patients, particularly with vomiting, can lose tremendous amounts of potassium, which may result in ileus.

DR CASTLEMAN: What about the level of potassium in uremia?

DR CURRENS: It may be high or low, it is usually high, but occasionally it may be low. Recently, a patient died in this hospital with a nonprotein nitrogen of 150 mg per 100 cc, and a serum potassium of 12 milliequiv per liter (normal, 3.5 to 5.0 milliequiv per liter). It is a possible explanation.

CASE 35392

PRESENTATION OF CASE

First admission. A thirty-nine-year-old housewife entered the hospital complaining of swollen legs.

At the age of fourteen the patient had severe pains in the feet and ankles. A heart murmur was noted, and she was kept in bed for about six months. With clearing of the joint pains she was allowed to resume normal activities but on doing so developed "Saint Vitus dance," described as purposeless twitchings of the hands and arms, which lasted about one and a half years, and then disappeared completely. The patient was well until the age of twenty-four, when, two weeks before the birth of her first child, she developed ankle edema that cleared spontaneously after delivery. She was then free of symptoms until one year prior to admission, when she developed palpitations and exertional dyspnea. Shortly before entry she noted ankle swelling, severe exertional dyspnea and orthopnea requiring three pillows, with almost weekly attacks of paroxysmal nocturnal dyspnea. There was no cough, chest pain, or fever.

Physical examination revealed marked engorgement and pulsation of the neck veins. Many moist rales were present throughout both lung fields. The heart rate was rapid and irregular, with an apical rate of 110 and a radial pulse of 96. There was enlargement of the heart to percussion and an apical systolic thrill. Harsh apical systolic and diastolic murmurs and a blowing diastolic murmur in the aortic area were heard. The liver edge was 5 cm below the costal margin. The ankles and calves showed marked pitting edema.

The temperature was 99.2°F, and the respirations were 24. The blood pressure was 174 systolic, 98 diastolic.

Laboratory studies on the urine showed a specific gravity of 1.018, with a trace of albumin. Blood studies, including the white-cell count, nonprotein nitrogen, carbon dioxide and total protein, were not remarkable. An electrocardiogram demonstrated auricular fibrillation alternating with idioventricular rhythm. X-ray studies of the chest showed a small amount of fluid in the left costophrenic angle and considerable generalized cardiac enlargement.

Following digitalization the patient improved steadily until two and a half weeks had elapsed, and then she suddenly developed severe pain in the right lower chest and hemoptysis. Roentgenograms revealed a large area and several smaller areas of increased density in the right lower lobe. Surgical interruption of both common femoral veins was done, but no clots were found. Improvement was slow but steady, and after three months the patient returned home on a regimen of digitals, ammonium chloride and weekly injections of mercurhydriol.

Second admission (four months later). The patient did well until approximately four months

In conclusion, I believe this patient had rheumatic heart disease, with mitral stenosis and regurgitation, aortic regurgitation and auricular fibrillation. Evidence of active rheumatic fever may have been found. Congestive heart failure was certainly present. In addition, I would postulate recurrent pulmonary emboli, perhaps arising from the right auricle, with terminal pulmonary embolization or thrombosis within the pulmonary arterial tree and cor pulmonale leading to death. I think the azotemia and albuminuria were more likely due to congestive failure than to complicating intrinsic renal disease. A "toxic" psychosis, with perhaps some element of lithium intoxication, seems the best explanation of the episodes of confusion and delirium so prominent at the time of her terminal illness.

CLINICAL DIAGNOSES

Rheumatic heart disease with mitral stenosis
Auricular fibrillation
Progressive cerebral thrombosis

DR MYERS'S DIAGNOSES

Rheumatic heart disease, with mitral stenosis
and regurgitation, aortic regurgitation and
auricular fibrillation
Active rheumatic fever?
Pulmonary embolism, from right-auricle thrombi,
with cor pulmonale
Toxic psychosis from lithium intoxication?

ANATOMICAL DIAGNOSES

Pulmonary embolism, massive, acute
Mural thrombi, both auricles
Endocarditis chronic active rheumatic, mitral
and aortic, with mitral stenosis
Healed pulmonary infarcts
Congestion of lung, liver and spleen
Cerebral emboli, microscopic
Cardiac hypertrophy right.
Renal infarct

PATHOLOGICAL DISCUSSION

DR CASTLEMAN Post-mortem examination showed an enlarged heart, weighing 430 gm. There was marked dilatation of both auricles and dilatation and hypertrophy of the right ventricle, which was about twice normal in thickness — findings characteristic of the mitral heart. This was confirmed when the heart was opened, the mitral orifice barely admitting the tip of the little finger. Although the aortic cusps were thickened and in places calcified, there was no evidence of interadherence to produce any stenosis. Microscopically, above the margins of both valves there was active fibroblastic proliferation consistent with chronic active rheumatic infection. Although I could find no Aschoff nodules in the myocardium, I believe the cellular proliferation in the valves indicates a process that was still in a healing stage.

As evidence of the auricular fibrillation we found mural thrombi in both auricular appendages, and these probably were the source of the emboli to the lungs from the right auricle and to the kidney and brain from the left. There were both old and recent emboli within the pulmonary circuit, the recent ones being in the main vessels and the immediate cause of death, the older ones were in the smaller vessels and in relation to healed infarcts.

In several microscopical sections of the cerebrum, there were many small arteries occluded by old recanalized thrombi as well as more recent occlusions, unquestionably representing emboli. There were a few small foci of infarction. There was no evidence of an endarteritis, and I believe that many of the cases of so-called rheumatic endarteritis are probably on an embolic basis. There were no changes to suggest a toxic process.

that led to the patient's death? Since the onset of her terminal illness was characterized by tremors and disorientation and the appearance of a pruritic dermatitis, one immediately wonders about medication. May we know what drugs she had been receiving between the second and third admissions? Had she been taking lithium chloride as a salt substitute?

DR BENJAMIN CASTLEMAN She had been followed in the Out-Patient Department and given digitalis, ammonium chloride and mercurial injections. In addition she had been put on a low-sodium diet and had been given a lithium chloride preparation starting about a month before her final admission to the hospital.

DR MYERS Do we know how much lithium chloride the patient actually consumed? Also, did she continue to receive the salt substitute after admission?

DR CASTLEMAN There is no record of the actual amount ingested. She did continue to receive the salt substitute ad lib after admission to the hospital.

DR MYERS It would be possible to explain this patient's coarse tremors and disorientation on the basis of lithium intoxication. She apparently was taking it for only a short time prior to the onset of her acute symptoms, but she may have taken far more than was recommended, as some patients do. Also we learn that her renal status was unsatisfactory, with a nonprotein nitrogen of 66 mg per 100 cc, so that the excretion of lithium may have been unusually poor. As far as I know lithium poisoning has not been associated with the appearance of a skin rash, however. Neurologic manifestations of digitalis toxicity, including restlessness, disorientation, delirium and tremors, in the absence of other evidence of digitalis poisoning have been reported, but these are certainly very rare and again would not account for the pruritic erythema of the skin. She had apparently not ingested bromides, barbiturates or salicylates. It seems highly unlikely that the mercurial injections can be implicated. Patients on the low-sodium diet may occasionally become weak, confused or comatose, with a high nonprotein nitrogen and low serum sodium level, but that was not the picture here. Although mental aberrations on the basis of cortical-vessel involvement in rheumatic fever have been considered to occur, the evidence for this is unsatisfactory, and the associated erythema as described

is not like that of the rheumatic erythemas ordinarily encountered. The neurologic examination was negative, and the evidence does not favor the occurrence of multiple cerebral emboli from the left auricle or from a focus of bacterial endocarditis on the mitral or aortic valves. I am forced to the conclusion that this patient had a "toxic" psychosis in association with congestive heart failure, cerebral anoxia and azotemia. Lithium intoxication may also have played a role. I cannot satisfactorily explain the skin rash, and that is disturbing.

We are still left with the problem of the final cause of death.

At the time of her final admission the patient exhibited signs of right-sided cardiac failure without evident pulmonary congestion. The heart murmurs were unchanged, and the auricular fibrillation was moderately well controlled as to ventricular rate. There was no elevation of temperature or marked leukocytosis, and the chest x-ray film failed to reveal fresh pulmonary infarcts. The appearance of right-axis deviation in the electrocardiogram, not mentioned as having been present at the time of the first admission, may have been on the basis of mitral stenosis and due to right ventricular strain resulting from repeated pulmonary emboli as well. The elevated nonprotein nitrogen may merely represent prerenal azotemia on the basis of congestive heart failure. What did urinalysis show at the time of the last admission?

DR CASTLEMAN The specific gravity was 1.012, with a +++ test for albumin and the sediment showed 15 to 20 epithelial cells per high-power field and a few white cells but no red cells.

DR MYERS Heart failure could also account for the presence of albuminuria. We seem to have no evidence, other than the rather low specific gravity, to suggest complicating renal disease.

The last few days in the hospital were marked by a rapid downhill course, with delirium followed by coma. She became progressively more cyanotic and dyspneic, tachycardia became more marked, and a sharp temperature elevation occurred just before death. Despite marked respiratory distress the lungs were clear. I believe that terminal pulmonary embolism or thrombosis in the pulmonary arterial tree may explain this picture. In such a case actual new pulmonary infarcts may or may not have occurred. Active rheumatism cannot be ruled out.

In conclusion, I believe this patient had rheumatic heart disease, with mitral stenosis and regurgitation, aortic regurgitation and auricular fibrillation. Evidence of active rheumatic fever may have been found. Congestive heart failure was certainly present. In addition, I would postulate recurrent pulmonary emboli, perhaps arising from the right auricle, with terminal pulmonary embolization or thrombosis within the pulmonary arterial tree and cor pulmonale leading to death. I think the azotemia and albuminuria were more likely due to congestive failure than to complicating intrinsic renal disease. A "toxic" psychosis, with perhaps some element of lithium intoxication, seems the best explanation of the episodes of confusion and delirium so prominent at the time of her terminal illness.

CLINICAL DIAGNOSES

Rheumatic heart disease with mitral stenosis

Auricular fibrillation

Progressive cerebral thrombosis

DR MYERS'S DIAGNOSES

SIGNERS OF THE PROTEST

THE signers of the Protest of January 31, 1949, to the American Medical Association have continued since that time to lead a loosely corporate existence. Their original protest was against the levying of the famous twenty-five dollar assessment unless or until some adequate guarantee could be given that the policies and methods of the Association in combating compulsory health insurance would be more constructive and progressive than previous indications had led one to expect.

The same unhappy flair for infelicitous publicity that characterized the actions of the House of Delegates in adopting the assessment and, at a subsequent meeting, in repudiating the Association's editor greeted the protest. As a result a number of physicians who had only the welfare of their profession at heart came under the suspicion of having betrayed organized medicine instead

of guarding its honor with more than ordinary zeal.

Since that time a number of the signers of the protest have paid the assessment—some, no doubt, because they acknowledged the legality of the levy, regardless of its purpose, others because of a reasonable assurance that the Association was really embarked on a constructive campaign for the equitable distribution of medical service. The announcement of a national representative health assembly to be held this fall gave promise also that the Association's twelve-point program, existing at present only as a statement of impeccable principles, might in reality become a program, devoted to action.

The signers of the protest have continued to interest themselves in health legislation, and have shown a commendable desire to keep informed on the subject. Most recent interest in this respect has had to do with the Flanders-Ives Bill (S 1970) and its identical companion House bills (4918 through 4924), introduced by Messrs Herter, Javits, Case, Nixon, Morton, Fulton and Hale. The opinion of the "signers" has been sought on this prospective legislation in the light of a statement made by Dr. George Baehr on behalf of the New York Academy of Medicine, at the public hearings before the Senate Committee on Education and Labor, on June 20, 1949.

The Academy, which, in 1946 and 1947, urged enactment of legislation "to provide federal grants-in-aid to the states for the study of state and local needs and the development of state and local programs designed to correct those deficiencies in accordance with acceptable federal standards," is not interested in maintaining the status quo. It is, on the contrary, "prepared to consider any change in the methods of rendering medical services and of payment for medical care which may be better for the people."

S 1970, according to Dr. Baehr, comes most nearly, of all the bills under consideration, to meeting all the Academy's requirements for a voluntary prepaid comprehensive medical-service plan. Two excellent features of the bill are the provisions for the gradual development of its program, with the encouragement of medical groups,

and the creation of a bipartisan federal health study and planning commission to make a survey of health service needs and report to Congress in 1953

The fears of the Subcommittee on National Legislation of the Massachusetts Medical Society, as expressed last May to Congressman Herter, are that this bill, if passed, would ultimately result in the absorption by the federal Government of voluntary, nonprofit, prepayment medical and hospital-care plans. No mention is made in it of employer contributions, nor is the method of financing clearly defined. Ostensibly subscribers would pay in accordance with their ability to pay, the chief financial burden being carried by those with greater-than-average incomes, who would pay in much more than they would take out.

What is obviously needed more than anything else, if the best health plan possible is to be devised for the nation, is a meeting of the most capable minds, without heat and without acrimony.

FOOD FOR THOUGHT

THE latest program undertaken by "CARE"—Cooperative for American Remittances to Europe, Inc.—is to provide food for the hungry intellects of Europe. Reduced indeed is the pabulum that nourishes the mind, for at no time in the history of the world have so many books been destroyed as in the past decade.

In Prague, as a result of the War, the Research Institute of Medical History of Charles University lost 16,000 of its 20,000 volumes. The Public Library of Corfu, Greece, lost 70,000 volumes. The University Library in Vienna lost 150,000, and the British Museum Library in London 250,000. The National and University Library of Strasbourg lost 300,000 of its prewar collection of 800,000 volumes, and 900,000 were destroyed at the University Library of Louvain, which had been devastated in 1914 and since rebuilt with American aid. The need for books, never satisfied, has become desperate.

CARE, having sent literally millions of food and textile packages overseas from Americans, now, in its "Food for the Mind" program, has its representatives in other countries, in co-operation with

those of UNESCO, collecting lists of the books in certain specified fields needed by the universities, libraries and technical schools of fourteen nations. Only new books are being sent, and these, published in English, are selected from a list prepared by a committee headed by Dr. Luther Evans, librarian of Congress, and composed of thoroughly qualified scientists and librarians. The categories covered include health and welfare, medicine, dentistry, applied science, nursing, agricultural science, veterinary science and English-language instruction. Deliveries are being made to institutions only, in Austria, Belgium, Czechoslovakia, Finland, France, Greece, Italy, Japan, Korea, the Netherlands, Norway, Great Britain, the three western zones of Germany and all Berlin, and negotiations with Poland are pending.

Contributions of money in any amount will be received by the CARE Book Program, 20 Broad Street, New York City, or by any CARE office in the country. Donors of ten dollars or more may specify the institution and country to which books shall be sent, and the category in which the books may fall, but not the titles.

With many freedoms lost, there are still those left to which the knowledge gained from books can lead the way.

DIABETES WEEK, 1949

DIABETES Week this year will commence on October 10 and will constitute a particular "week" to which none need object. The purpose of its observance is an unusual, concentrated effort to find as many as possible of the million undiscovered diabetic persons in the country.

The most important specific function of this drive will be the performance of the simplest fundamental test for the discovery of diabetes—the examination of the urine for the presence of sugar of as many persons as can be persuaded to have the test performed. This testing will be done generously, freely, and by as many agencies and under as many auspices as may seem wise and practicable.

The important agent, however, must be the physician, who has available the necessary follow-up technic and who will find in this occasion an op-

SIGNERS OF THE PROTEST

THE signers of the Protest of January 31, 1949, to the American Medical Association have continued since that time to lead a loosely corporate existence. Their original protest was against the levying of the famous twenty-five dollar assessment unless or until some adequate guarantee could be given that the policies and methods of the Association in combating compulsory health insurance would be more constructive and progressive than previous indications had led one to expect.

The same unhappy flair for infelicitous publicity that characterized the actions of the House of Delegates in adopting the assessment and, at a subsequent meeting, in repudiating the Association's editor greeted the protest. As a result a number of physicians who had only the welfare of their profession at heart came under the suspicion of having betrayed organized medicine instead

of guarding its honor with more than ordinary zeal.

Since that time a number of the signers of the protest have paid the assessment—some, no doubt, because they acknowledged the legality of the levy, regardless of its purpose, others because of a reasonable assurance that the Association was really embarked on a constructive campaign for the equitable distribution of medical service. The announcement of a national representative health assembly to be held this fall gave promise also that the Association's twelve-point program, existing at present only as a statement of impeccable principles, might in reality become a program, devoted to action.

The signers of the protest have continued to interest themselves in health legislation, and have shown a commendable desire to keep informed on the subject. Most recent interest in this respect has had to do with the Flanders-Ives Bill (S 1970) and its identical companion House bills (4918 through 4924), introduced by Messrs Herter, Javits, Case, Nixon, Morton, Fulton and Hale. The opinion of the "signers" has been sought on this prospective legislation in the light of a statement made by Dr. George Baehr on behalf of the New York Academy of Medicine, at the public hearings before the Senate Committee on Education and Labor, on June 20, 1949.

The Academy, which, in 1946 and 1947, urged enactment of legislation "to provide federal grants-in-aid to the states for the study of state and local needs and the development of state and local programs designed to correct those deficiencies in accordance with acceptable federal standards," is not interested in maintaining the status quo. It is, on the contrary, "prepared to consider any change in the methods of rendering medical services and of payment for medical care which may be better for the people."

S 1970, according to Dr. Baehr, comes most nearly, of all the bills under consideration, to meeting all the Academy's requirements for a voluntary prepaid comprehensive medical-service plan. Two excellent features of the bill are the provisions for the gradual development of its program, with the encouragement of medical groups,

and the creation of a bipartisan federal health study and planning commission to make a survey of health service needs and report to Congress in 1953

The fears of the Subcommittee on National Legislation of the Massachusetts Medical Society, as expressed last May to Congressman Herter, are that this bill, if passed, would ultimately result in the absorption by the federal Government of voluntary, nonprofit, prepayment medical and hospital-care plans. No mention is made in it of employer contributions, nor is the method of financing clearly defined. Ostensibly subscribers would pay in accordance with their ability to pay, the chief financial burden being carried by those with greater-than-average incomes, who would pay in much more than they would take out.

What is obviously needed more than anything else, if the best health plan possible is to be devised for the nation, is a meeting of the most capable minds, without heat and without acrimony.

FOOD FOR THOUGHT

THE latest program undertaken by "CARE"—Cooperative for American Remittances to Europe, Inc.—is to provide food for the hungry intellects of Europe. Reduced indeed is the pabulum that nourishes the mind, for at no time in the history of the world have so many books been destroyed as in the past decade.

In Prague, as a result of the War, the Research Institute of Medical History of Charles University lost 16,000 of its 20,000 volumes. The Public Library of Corfu, Greece, lost 70,000 volumes. The University Library in Vienna lost 150,000, and the British Museum Library in London 250,000. The National and University Library of Strasbourg lost 300,000 of its prewar collection of 800,000 volumes, and 900,000 were destroyed at the University Library of Louvain, which had been devastated in 1914 and since rebuilt with American aid. The need for books, never satisfied, has become desperate.

CARE, having sent literally millions of food and textile packages overseas from Americans, now, in its "Food for the Mind" program, has its representatives in other countries, in co-operation with

those of UNESCO, collecting lists of the books in certain specified fields needed by the universities, libraries and technical schools of fourteen nations. Only new books are being sent, and these, published in English, are selected from a list prepared by a committee headed by Dr. Luther Evans, librarian of Congress, and composed of thoroughly qualified scientists and librarians. Donors of ten dollars or more may specify the institution and country to which books shall be sent, and the category in which the books may fall, but not the titles.

With many freedoms lost, there are still those left to which the knowledge gained from books can lead the way.

DIABETES WEEK, 1949

DIABETES Week this year will commence on October 10 and will constitute a particular "week" to which none need object. The purpose of its observance is an unusual, concentrated effort to find as many as possible of the million undiscovered diabetic persons in the country.

The most important specific function of this drive will be the performance of the simplest fundamental test for the discovery of diabetes—the examination of the urine for the presence of sugar of as many persons as can be persuaded to have the test performed. This testing will be done generously, freely, and by as many agencies and under as many auspices as may seem wise and practicable.

The important agent, however, must be the physician, who has available the necessary follow-up technic and who will find in this occasion an op-

portunity to demonstrate publicly that his real concern in the practice of medicine is that of service rather than reward. This is a lesson to be impressed upon a somewhat skeptical public that is inclined to find actions more eloquent than words.

PRIZE-ESSAY COMPETITION

THE *Journal* announces that a prize-essay contest will be open to all members of the class of 1950 registered in any medical school approved by the Council on Medical Education and Hospitals of the American Medical Association. The subject of the competition will be "Recent Advances in the Recognition, Treatment and Control of Poliomyelitis."

As in the previous competition, the purpose is to encourage good medical writing as well as to promote the collection of scientific material, and particular weight will therefore be given to such qualities as clarity, simplicity and general literary distinction. The conditions of the contest are unchanged: manuscripts should be between four and five thousand words in length, clearly typewritten in English, double or triple spaced, with references listed at the end in numerical sequence according to the form used by the *Quarterly Cumulative Index Medicus*. Papers must be in the hands of the editor by March 15, 1950. All manuscripts will become the property of the *Journal*.

The prize for the best essay among those submitted for consideration will be \$100. The paper will again be published in the "Medical Progress" series, and the author will receive a hundred free reprints.

The second prize will again consist of a two-year subscription to the *Journal*.

The prize-winning essay for 1949, entitled "Preventive Medicine," by Dr. Miriam D. Manning, of the class of 1949 at Tufts College Medical School, appeared in the June 30 issue of the *Journal*. It is hoped that the essays for 1950 will come up to the high standard set by Dr. Manning's essay, which demonstrated the quality of medical writing that physicians should be capable of and which the judges unanimously awarded first prize.

By the influence of a pretended clairvoyant mesmerizing female over vulgar minds, an elaborate and patient examination of the manure of a large stable was recently made in Boston, to find the body of a missing expressman, whom she declared had been murdered, and was there concealed. On Monday, of last week, the defunct reappeared in the city, in excellent condition!

DEATHS

LANG — Walter E. Lang, M.D., of Westboro, died on September 11. He was in his sixty-sixth year.

Dr. Lang received his degree from Hahnemann Medical College and Hospital of Philadelphia in 1910. He was a member of the New England Society of Psychiatry and the American Psychiatric Association and a fellow of the American Medical Association.

His widow, a daughter and a son survive.

MANDELL — Augustus H. Mandell, M.D., of New Bedford, died on September 3. He was in his eighty-second year.

Dr. Mandell received degrees from New York University Medical College in 1897 and Cornell University Medical College in 1899. He was resident physician at Sassaquin Sanatorium in New Bedford.

His widow survives.

McFEE — William D. McFee, M.D., of Haverhill, died on September 7. He was in his seventy-fifth year.

Dr. McFee received his degree from University of Vermont College of Medicine in 1897. He was president of the American Academy of Physical Medicine and was a fellow of the American Medical Association.

His widow, four daughters and two sisters survive.

CORRESPONDENCE

STUDY OF TWINS

To the Editor The study of twins is of great value in providing information concerning the respective importance of hereditary predisposition and environmental influences in disease in man. The results of the use of this method have shown a hereditary predisposition to tuberculosis, diabetes and tumor formation, and a high, medium or low intelligence quotient.

There is some *a priori* evidence of a hereditary predisposition for peptic ulcer. Only 6 cases of peptic ulcer in either or both of monozygous or dizygous twins have been reported in the readily accessible literature. Since twins are born in 1 of 86 births and identical twins in 1 of 344 births and the general incidence of ulcer is from 5 to 10 per cent, there should be plenty of material available.

I should like to ask physicians to co-operate in assembling such material by sending me information regarding cases in which one or both twins develop peptic ulcer, the site of the ulcer, the age of the patient at onset of the ulcer, the type of twins (monozygous or dizygous), the sex and date of birth of the twins and the number and age of the brothers and sisters and the absence or presence of ulcer in each.

DIFFICULTIES OF GENERAL PRACTICE

To the Editor Having recently made the transition from one of the larger teaching hospitals to a rural general practice, I feel called upon to comment on your editorial of August 11 entitled "Education of the Family Physician."

As one of a bewildered group of young men who have recently finished medical school, I was faced with the problem of specialization. My environment and conditioning has been such that, seemingly, the man who was in general practice was a man who had unsuccessfully competed for some type of residency and so was ungracefully thrust out into the world to make a living with the unspecialized knowledge that he had managed to accumulate. I, too, had been guilty many times of referring patronizingly on hospital records, to the "L M D."

However, with the passage of time and the increasing size of my family, it soon became apparent that I should not be able to go on with my training—that soon I must earn a living. And medicine had reached the stage where it could be said that the "renaissance of the general practitioner" was upon us. There was the increasing agitation by the American Medical Association for more general practitioners, specialization had begun to be viewed with alarm, there had been created a General Practitioner of the Year Award, and a new group, the American Academy of General Practice, had made its appearance. It is in this favorable era that I have begun my general practice.

And after four months of rural general practice I believe that I can begin to make some comments on the status of my medical education. First and foremost, it is not advancing as it used to. The editorial referred to above glibly states that "The family doctor is likewise to blame by trying to do too much and becoming so busy, he cannot keep up with attendance at meetings or with medical literature. Instead he would do well to put such educational activities on a required list each week." When one works seven days a week for twelve to fourteen hours and more a day, one finds it difficult to keep up with what is going on. My journals are only glanced through because I find myself too busy. Is it the patients' fault? I don't know. Perhaps in a while the novelty of "the new doctor" will wear off. But what I am getting at is that, through apparently no fault of my own, I have become too busy and don't know what to do about it. One can hardly refuse to see patients in an area like this if they call one.

Secondly, educational opportunities for the rural practitioner, particularly in this area, are almost nil. There are no hospitals that contain ward beds for me to visit and observe. What shall I do? When one is located hundreds of miles from teaching centers, getting to them is more easily said than done, especially if one dare not leave because of critically ill patients who cannot be turned over to anyone during one's absence.

Finally, membership in the American Academy of General Practice, a purported stimulus to education, excludes the neophyte who is just beginning his practice. He must have completed three years of general practice before being considered for membership. This hardly leads to encouragement for a man to continue his education if he is excluded from the few educational opportunities that may be open to others but not to him, simply because he has not "put in enough time" to become a member. And, in three years, who knows whether the requirements for membership will have been made even more rigid and I, and men like me, will be unable to qualify for membership. Yesterday there was no American Board of Proctology.

What is the answer? Certainly, it cannot be that the general practitioner in an area like this is at fault. Perhaps it is society, or perhaps it is the physicians themselves who have banded together and made tight centers of learning, meccas toward which many of us aspire but for the nonce are unable to enjoy. There are many like myself, I am sure, who would like to be heard. There must be because my colleagues who are near me have the same problems. Are we to blame for our stagnation? Perhaps I am rationalizing when I say, "No."

BOOK REVIEWS

Psychiatry A short treatise By William A O'Connor, L M S S A (Lond), D P M (Lond) 8°, cloth, 380 pp Baltimore Williams and Wilkins Company, 1948 \$9.00

For an adequate review of this textbook one would need to know not necessarily the literature and history of the development of psychiatry as practiced in Great Britain, but rather the attitude and emotional reaction toward psychiatry and its therapeutic approach as manifested by the psychiatrists of today. The author states, both in the preface and in the body of the text, that his approach is that of psychosomatic medicine. The impression is gained, however, that here is a man torn between two worlds: the organic and the functional, or the descriptive and the dynamic analytical.

On the whole, the material is well organized. Too often, definition of terms and mechanisms are left to haphazard search on the part of the beginner. The chapter on "Symptoms of Mental Disease" and that on "Psychic Mechanisms" are a distinct step forward in the understanding of a new subject. To present the various paranoid reactions as a group is probably well justified and leads to clearer thinking, although one still must consider it a type of schizophrenia, as long as the official classification continues, and the author rightly does so. "Analytic Therapy and Theory" is also a logical introduction inasmuch as the author tends toward an eclectic approach. Other than the above, the general outline of each chapter devoted to each of the major groups of the psychoses (namely "History," "Aetiology," "Psychopathology," "Symptomatology," "Diagnosis," "Prognosis" and "Treatment") is systematic and conducive to clear thinking.

Only a beginner can tell what a beginner gets out of an introductory text to psychiatry. Had there been no effort by the author to set forth a thesis, one would have little to remark about, either for originality or lack of it. As it is, there is the curious feeling that the past still influences too much, that description takes the place of dynamics, that psychiatry is still the handmaiden of neurology and that the functional is still overshadowed by the organic. Whether one or the other should prevail is entirely beside the point. One gets a little of the impression one does of "Lot's Wife." The author intellectually is walking into the future, but emotionally his face is turned to the past.

Conditioned Reflexes and Neuron Organization By Jerzy Konorski. Translated from the Polish under the author's supervision by Stephen Garry 8°, cloth, 267 pp, with 18 illustrations Cambridge, University Press, New York, Macmillan Company, 1948 \$4.00 (Cambridge Biological Studies)

This book undertakes the task of "attempting to extend the Sherrington conception of the functioning of the nervous system to the field of higher nervous activity." An effort is made to close the gap between Sherrington and Pavlov in the field of neurophysiology. The accomplishment is particularly commendable because the work was made much more difficult by the loss of original manuscripts and research notes as a result of war damage to the Nencki Institute of Experimental Biology in Poland. The material is presented in a clear, concise style when allowances are made for the fact that this is a translation from the Polish language. The translator should be complimented for the precise way in which he has executed his task. This short book is provocative and encourages a more adequate approach to the problem of higher cerebral integration. It definitely is a landmark for further research in the field of neurophysiology.

The author finds no conflict with the neuron theory of the functioning of the nervous system. The ideas developed in his research fall into the framework of this theory. However, the point is presented that the activity of the cerebral cortex is associated not only with the idea of excitability and the inhibition of transmission of impulses but also with new paths for these stimuli to travel on their complicated journey.

Three assumptions are made to account for these properties. The first is that "the elaboration of a condition reflex consists in the formation of new connexions in the brain, or rather that there can be the formation and multiplication of synapses between coupled cerebral centres." Secondly, it is postulated that if "a combination of excitations which results in a plastic change is not repeated within a certain period,"

the regression of this change may occur. Thirdly, "internal inhibition being a process that arises with non-reinforcement of the established condition reflex consists in the formation of new synaptic connexions of an inhibitory nature, independently of the already existing excitatory synaptic connexions." Although an attempt is made to correlate the physiology of the higher nervous activity with neurophysiology, the author well recognizes the limitations of his own presentation, several of which he mentions. He states that he is concerned in this book with "lowest levels of cortical coordination" and that he has come up against many facts that because of their complexity are not fully covered by the principles he attempts to lay down. He presents a challenge of trying to understand cortical and subcortical cerebral function in relation to human mental activity. He seems to believe that the physiology of the higher nervous activity is now at the stage that physics reached several centuries ago.

The format of the book is good, and a good index covers a rather general table of contents. The reader is able to become familiar with much of the Russian literature, which is difficult to translate. In spite of some of the verbosity that may be attributed somewhat to the difficult task of translation, this book is recommended for those who are interested in the complicated field of cerebral physiology.

Reproduction and Survival By R. Christie Brown, M.B., M.S., F.R.C.S., F.R.C.O.G. 12^o, cloth, 108 pp. London: Edward Arnold and Company, 1948. \$2.25.

In this remarkable monograph, the author presents a well known British obstetrician's concept of the philosophy of reproduction as a means of racial survival, viewing embryology as a biologic phenomenon. Reproduction is a racial, not an individual, process whose objective is to guarantee survival of the species. In the contest for survival, in which the individual is merely a pawn in the game, various patterns of reproduction, adapted to the environment, have been employed. Civilization mitigates some of the stresses of nature in the struggle to live in a highly hazardous and competitive universe, and physical death is deflected by the rejuvenation of tissues at reproduction. But civilization introduces new hazards of its own, and medical science sometimes makes possible the temporary survival of the unfit and the perpetuation of undesirable qualities. Abundant reproduction, continuous variation and unhampered natural selection are the essentials of racial survival and evolutionary improvement amid the thrusts and parries of a dangerous world. To a certain limited extent parental care, co-operation and sacrifice may substitute for free reproduction, but declining human birth rates are the danger signals of progressive racial deterioration and decay. The only physical immortals are the species and the germ cells, the fateful race of zygotes. Man, who alone has developed an organism capable of harboring spirit, is more concerned with the individual than with the species, but nature is concerned only with the survival of living forms.

*So careful of the type she seems,
So careless of the single life*

Dementia Praecox: The past decade's work and present status. A review and evaluation. By Leopold Bellak, M.D. With a foreword by Winfred Overholser, M.D. 8^o, cloth, 456 pp., with 8 illustrations. New York: Grune and Stratton, 1948. \$10.00.

As stated in the subtitle, Dr. Bellak presents in this work a review and evaluation of the work of the past decade concerning the problem of schizophrenia. He presents a well systematized and readable review of all the major investigative work that has been done in the past ten years, and correlates the numerous isolated facts from both the organic and the psychogenic standpoints concerning the etiology, psychogenesis and psychopathology of schizophrenia. In addition, he gives a well integrated evaluation of the various forms of therapy and technique.

This work presents in one volume the results of extensive research concerning this problem and therefore provides a valuable summary of present knowledge of schizophrenia. The volume should be of great value to those interested in this problem and of equal, if not greater, importance to those who are initiating their study of schizophrenia, presenting

as it does a complete summary of existing knowledge and directing the reader's attention to future avenues of investigation.

Muscles: Testing and function. By Henry O. Kendall and Florence P. Kendall. 4^o, cloth, 278 pp., with 162 illustrations. Baltimore: Williams and Wilkins Company, 1949. \$7.50.

This atlas on the testing and function of muscles is refreshingly clear and easy to read. The photographs of the contracting muscle on the subject are excellent and give a vivid picture of the movement performed. The muscles of the upper and lower extremities, the back, the abdomen and face are shown and described in turn. For completeness, one would have liked to see a fuller description of the muscles of the eye and the buccal cavity. But the testing and training of these muscles is probably outside the function of the physiatrist. There is a concise descriptive text accompanying each photograph. There are charts of the origin and insertion of the varying inner ration of muscles. The methods of recording muscular efficiency are carefully described. This work appears at an appropriate time when there is renewed interest and improved techniques for the rehabilitation of the handicapped. Its careful arrangement and illustration should recommend it for the training and guidance of physicians and physiotherapy technicians as a valuable guide in assessing physical disabilities. The Kendalls are to be congratulated for producing so useful and pleasing a treatise.

Present Concepts of Rehabilitation in Tuberculosis. A review of the literature, 1938-1947. By Norvin C. Kiefer, M.D., M.P.H. 8^o, cloth, 398 pp. New York: National Tuberculosis Association, 1948. \$3.50.

This book is a compilation of the literature on the subject of rehabilitation of the tuberculous. Fifteen of its sixteen chapters are abstracts of the current literature, and the last chapter is devoted to the comments of the author. This literature has sprung up chiefly in the past decade or fifteen years. It deals with the extent of this problem, the eligibility for rehabilitation services, suitable work for ex-patients, the contagious aspect of the disease and so forth. The administration as well as the cost of such a program also receives attention. The psychologic and the spiritual aspects of dealing with the chronically ill are also considered.

Although much has been written on rehabilitation and the author has abstracted more than a thousand articles, very little has actually been accomplished. This subject lends itself very well to lengthy discussions and seminars, but the actual concrete program of rehabilitation in the full sense of the word is beset with many difficulties. The protean nature of this disease and the contagiousness as well as the higher age of the present-day sanatorium population are major obstacles. However, the National Tuberculosis Association, through its state and city organizations, has dedicated itself to this task and made rehabilitation one of its goals. At least the community is made aware of its responsibilities to the handicapped person. Much education will be required on the part of labor unions and industries, as well as in legislative halls, regarding compensation laws, for the problem of employment of the handicapped to be solved.

This book is comprehensive in its scope and deals adequately with the new and very difficult subject of rehabilitation. The author knows his subject and speaks with authority on the various phases of a complicated and difficult process. This book should prove useful to all tuberculosis workers.

The Story of Medicine. By Joseph Garland, M.D. 8^o, cloth, 259 pp., with illustrations. Boston: Houghton Mifflin Company, 1949. \$2.75.

In this short work the author has not undertaken a complete, systematic history of medicine, like those by Fielding Garrison and Cecilia Mettler. Rather, in a series of twenty-two editorial essays, he presents a popular synopsis review of the evolution of medical practice and science from the time of the prehistoric medicine man to the present day of specialists, of sulfonamides, of antibiotics, of blood fractionation and of radioactive isotopes. But he is concerned not merely with achievements but also with human personalities, and, without detailed biography, he recreates and revitalizes many "of the great physicians in the long line that has passed through the pages of medical history." Particularly is he to

be praised for the happy literary style of his work, and for his felicitous quotations from Homer, Martial, Shakespeare, "Everman" and others. The book is well illustrated with twenty-three admirable original line drawings by Erwin Austin, and has a bibliography of thirty-two well selected titles. We are indeed fortunate to possess this fascinating volume by the editor of the *New England Journal of Medicine*.

Clinical Auscultation of the Heart By Samuel A Levine, M.D. and W. Proctor Harvey, M.D. 8°, cloth, 327 pp., with 286 illustrations. Philadelphia: W. B. Saunders Company, 1949. \$6.50.

This book brings to the student and the general practitioner the results of a long and fruitful experience in cardiovascular auscultation. It is divided into four major sections: heart sounds, cardiac irregularities, cardiac murmurs and miscellaneous auscultatory findings. The last include fifteen conditions in which auscultation may be useful. The title is more restrictive than the subject matter, since the discussion is by no means limited to auscultation. Treatment, for example, is outlined for all the cardiac arrhythmias and the x-ray findings in the congenital anomalies are described. Phonocardiograms are used very freely, but are correlated with electrocardiograms and with no other reference tracings such as phlebograms, which are essential in the analysis of diastolic phenomena. The illustrations are at times so reduced in size, and the sound tracings recorded at such slow speed, as to give little indication of the value of qualitative phonocardiography with modern techniques. This however, does not detract from the sound, clinical basis of the book. If the reader masters the stethoscopic technique, the auditory discrimination and the fundamental logic of these authors, most of the conditions described will not require graphic analysis. Outstanding are the discussions of gallop rhythms and systolic murmurs. The book can be recommended as a valuable guide to anyone aspiring to auscultatory perfection.

Lung Dust Lesions Versus Tuberculosis By Lewis G. Cole, M.D. 4°, cloth, 474 pp., with 428 illustrations. White Plains, New York: American Medical Films, Incorporated, 1948. \$10.00.

The author is a prolific writer and investigator of the old school, combining practical clinical knowledge with pure science. For years he has pioneered in the field of roentgenology. More recently, his chief interest has been the pathology of the lungs as related to pneumoconiosis. He writes in a very delightful conversational style that makes for easy reading.

This is not a book on dust lesions or on tuberculosis as applied to its clinical aspects. The author deals chiefly with the intricacies of pathological interpretations of dust lesions in the lungs such as silicosis, tuberculosis and silicotuberculosis. According to him, many dusts other than silica cause lung dust lesions. In persons exposed to coal, talc, iron, copper, beryllium and so forth, inhalation of such dusts, especially if they are also laden with micro-organisms, may cause fibrosis of the lungs. He also insists that chronic infections of the lungs and even tuberculosis cannot be distinguished pathologically from silicosis by the conventional light-field method of present-day microscopical examination. He believes that only by use of cross polaroid technique or cross nikols, especially lighted with a technique evolved by him, can silicosis be definitely distinguished from tuberculosis. He also deprecates the fact that patients with silicosis are kept from their occupations during the early stage of the disease, thus being unnecessarily deprived of their livelihood.

Many x-ray and pathological illustrations, excellently reproduced, accompany the text.

This book should be of particular interest to the research pathologist especially interested in the field of pneumoconiosis.

Considerable more research and orientation in the field of industrial medicine will be needed before the author's view can be accepted. He apparently loves a good argument, and he has left himself wide open for many a controversy.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Rheumatic Fever: Nursing care in pictures By Sabra S. Saller, R.N., consultant nurse, rheumatic-fever program, Virginia State Health Department and assistant professor of public-health nursing, Medical College of Virginia. 8°, cloth, 151 pp., with 204 illustrations. Philadelphia: J. B. Lippincott Company, 1949. \$3.50.

This manual on the care of children suffering from rheumatic fever is written primarily for parents. The methods of present-day treatment are explained in detail, and the illustrations are self-explanatory. It is intended as a guide, with the understanding that all care and procedures should be based on specific orders from the physician in charge. An introduction on rheumatic fever from a medical point of view is written by Dr. Reno R. Porter, assistant professor of medicine and director of the Cardiac Foundation of the Medical College of Virginia, and consulting cardiologist, Virginia State rheumatic-fever program. The remaining chapters, written by Mrs. Saller, who has been a special rheumatic-fever nurse with the Virginia Board of Health, since 1941, are devoted to the bed-rest treatment, personal care of the patient, care activities, diet, medications and treatment, and home teaching of school subjects. There is also a chapter on the social and emotional factors in the disease. The type and printing are excellent, but the ring type of binding is not suitable for a volume subject to hard usage. There is a good index. The manual should be in all public libraries and in the possession of parents with children suffering from rheumatic fever.

Clinical Aspects and Treatment of Surgical Infections By Frank L. Meleney, M.D., associate professor of clinical surgery, College of Physicians and Surgeons, Columbia University and associate visiting surgeon, Presbyterian Hospital, New York City. With a foreword by Allen O. Whipple, M.D. 8°, cloth, 840 pp., with 287 illustrations. Philadelphia: W. B. Saunders Company, 1949. \$12.00.

This special work covers the whole field of surgical infections from head to foot. It is intended as a companion volume to the author's *Treatise on Surgical Infections*, published in 1948. The material is well organized, and the text is well written. Numerous case histories are interspersed throughout the text. Selected lists of references are appended to the various chapters. There is a comprehensive author-subject index of fifty-eight pages. The book is well published and should be in all medical libraries and available to all surgeons.

Obstetric Analgesia and Anesthesia: Their effects upon labor and the child By Franklin F. Snyder, M.D., associate professor of obstetrics and associate professor of anatomy, Harvard Medical School. 8°, cloth, 401 pp., with 114 illustrations and 18 tables. Philadelphia: W. B. Saunders Company, 1949. \$6.50.

This new work is essential for all obstetricians and anesthesiologists. The material is well arranged and well written. The text is divided into two parts: respiratory injuries of the child, and the treatment of pain during labor. The first part discusses in detail the respiratory injuries before birth, including intrauterine pneumonia, atelectasis and asphyxia. The second considers all the anesthetics used during labor. Lists of references are appended to the various subjects, and there is a good index. The book should be in all medical libraries.

Your Child or Mine: The story of the cerebral-palsied child By Mary L. H. Burton, executive secretary of the Westchester Cerebral Palsy Association. In collaboration with Sage H. Jennings. 12°, cloth, 64 pp., with illustrations. New York: Coward-McCann, Incorporated, 1949. \$1.25.

This small volume relates the case histories of 6 children afflicted with cerebral palsy. It is written for the laity and shows what can be done for such children, especially socially,

if they receive the proper attention. The text is concluded with a list of cerebral-palsy associations and clinics. The book does not attempt to prescribe medically or surgically for the children. There is a short glossary of terms and a list of books and articles for further reading.

Diabetic Menus, Meals and Recipes By Betty M. West 8° cloth, 254 pp. Garden City, New York: Doubleday and Company, Incorporated, 1949. \$2.95.

This dietary manual was written primarily for diabetic patients and their families. Mrs. West acquired her knowledge at first hand, since she is a diabetic housewife. The soundness of her cookbook is attested by Dr. Rypins, a well known authority on diabetes. The book is well published, and there is a good index. It should prove valuable to those for whom it was written.

NOTICES

ANNOUNCEMENTS

Dr. Edmund F. Finnerty, Jr., announces the opening of his office for the practice of dermatology at 482 Commonwealth Avenue, Boston.

Dr. Aldo A. Luisada announces his appointment as assistant professor of medicine and program director of cardiology at University of Chicago School of Medicine, 710 South Wolcott Avenue, Chicago 12, Illinois, and the termination of his practice at 483 Beacon Street, Boston, on October 1, 1949.

Dr. William A. Lynch announces the opening of an office for the practice of obstetrics and gynecology at 1101 Beacon Street, Brookline, Massachusetts.

Dr. Albert O. Seeler announces the opening of an office for the practice of internal medicine at 1 Craigie Street, Cambridge.

SUFFOLK DISTRICT WOMAN'S AUXILIARY

The first meeting of the 1949-1950 season of the Suffolk District Woman's Auxiliary will be held on Thursday, October 6, at 2:30 p.m., in Sprague Hall, Boston Medical Library. The speakers will be Dr. A. J. A. Campbell, president of the Suffolk District Medical Society, and Miss Mary Jo Kraft, health education consultant for the United States Public Health Service, whose subject will be "How Doctors' Wives Can Help in the Tuberculosis Detection Campaign." Tea will be served after the meeting.

GREATER BOSTON MEDICAL TECHNOLOGISTS ASSOCIATION

A meeting of the Greater Boston Medical Technologists Association will be held in the lecture hall of the Boston Lying-in Hospital, 221 Longwood Avenue, Boston, on Tuesday, October 4, at 7:30 p.m. Dr. T. Hale Ham will speak on the subject "The Mechanism and Diagnosis of Hemolytic Anemias."

VETERANS ADMINISTRATION COURSE IN CLINICAL ELECTROCARDIOGRAPHY

A course in clinical electrocardiography will be given by Dr. David Littmann at the Veterans Administration Hospital, West Roxbury, Massachusetts, on Fridays from 4 to 5 p.m., beginning October 7.

Interested physicians and new students are invited.

NEW YORK ACADEMY OF MEDICINE

The Twenty-Second Graduate Fortnight of the New York Academy of Medicine will be held October 10 through 21, the subject being "Advances in Diagnostic Methods." The program includes morning panel discussions, afternoon hospital clinics, evening addresses and scientific exhibits and demonstrations.

Fellows of the Academy will be furnished registration cards without application. For others, a registration card will be sent upon receipt of check for ten dollars, payable to the Academy, and forwarded to New York Academy of Medicine, 2 East 103rd Street, New York 29, New York.

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING THURSDAY, OCTOBER 6

THURSDAY OCTOBER 6

2:30 p.m. Suffolk District Woman's Auxiliary. Sprague Hall, Boston Medical Library.

FRIDAY OCTOBER 7

*9:00 a.m.-12:00 p.m. Combined Medical and Surgical Staff Rounds. Peter Bent Brigham Hospital.

*12:00 p.m. X-Ray Conference. Margaret Jewett Hall. Mount Auburn Hospital, Cambridge.

*1:30 p.m. Tumor Clinic. Out Patient Department. Mount Auburn Hospital, Cambridge.

*4:00-5:00 p.m. Veterans Administration Course in Clinical Electrocardiography. Veterans Administration Hospital, West Roxbury.

MONDAY OCTOBER 10

*11:30 a.m.-12:15 p.m. Chest X-Ray Conference. South End Health Unit, 57 East Concord Street, Boston. Dr. Cleveland Floyd to charge.

*12:15-1:15 p.m. Clinicopathological Conference. Mayo Amphitheater, Peter Bent Brigham Hospital.

TUESDAY OCTOBER 11

*12:15-1:15 p.m. Cholecystoenterological Conference. Peter Bent Brigham Hospital.

*1:30-2:30 p.m. Pediatric Rounds. Burnham Memorial Hospital for Children, Massachusetts General Hospital.

*Open to the medical profession.

NATIONAL HEALTH SERVICE—RECOMMENDATIONS OF THE HOOVER COMMISSION*

HUGH R. LEAVELL, M.D., D.R.P.H.†

BOSTON

FORMATION of the Commission on Organization of the Executive Branch of the Government, more widely known as the Hoover Commission, was authorized by the eightieth Congress. Its duties were to investigate activities of the Executive Branch with the objectives of limiting expenditures as far as possible consistent with proper performance of essential services, doing away with overlapping and duplication, consolidating similar services and abolishing unnecessary ones, and defining the limits of executive function. The President appointed four members of the Commission, four were appointed by the President of the Senate, and four by the Speaker of the House of Representatives. Twenty-three task forces or committees were set up by the Commission to study various federal activities. One of these was the Committee on Medical Services of which the Honorable Tracey S. Voorhees was chairman. The Commission was obviously not obligated to accept all the findings of its task forces. Major recommendations of the Committee on Medical Services, however, were accepted though the Commission itself divided on certain matters, some members presenting their views in minority reports.

Medical and public-health operations of the federal Government during the 1948 fiscal year cost one and a quarter billion dollars. Three major agencies spent most of this money: the Veterans Administration 61 per cent, the armed forces 20 per cent, and the Federal Security Agency 14 per cent. Of the total expenditure, 85 per cent was for direct medical care, 4 per cent for research, and the rest for public-health services, training and administration. Some 24,000,000 Americans are beneficiaries to a greater or less degree of the federal medical care program. Eighteen and a half million veterans make up the largest group and stand in a somewhat middle position between the 3,000,000 members of the armed forces with their dependents, in addition to merchant seamen for whom complete medical care is provided, and the 2,000,000 federal civilian employees receiving only an industrial health service.

Many more weaknesses were found in the medical care program of the federal Government than in public health and research. Some major weaknesses are especially noteworthy: agencies compete with each other for scarce personnel, hospitals are constructed without an over-all plan, and facilities available are not utilized to maximum efficiency. The quality of medical care provided by different agencies varies considerably. Congress has failed to define a clear policy on beneficiaries. The best use of private practitioners and university medical personnel is not made in the medical care program. Preventive medicine and research are not emphasized as they should be if the greatly increasing costs of medical care are to be reduced. Federal assistance needed so much by medical schools and other health-training institutions is lacking.

Since no one person is responsible for the over-all federal health operations, there is competition among agencies for scarce medical and technical personnel. At the time the report was made the Veterans Administration had 5600 beds closed because of insufficient personnel to staff existing facilities. In the armed forces the shortage is particularly acute with the idea general that a draft may be necessary to provide medical personnel, since voluntary recruitment is failing to meet the need. Even with a draft applying only to younger doctors, there would be a shortage of specialists.

Hospitals are being constructed by various federal agencies without relation to the plans or needs of other federal agencies or to those of voluntary, state and local governmental hospitals. Construction costs vary greatly, ranging from \$20,000 to as high as \$51,000 per bed, with the estimated cost to voluntary hospital construction at the present time about \$16,000 per bed. Nearly half the hospitals of the Veterans Administration are planned to be built in areas where experience has shown that staffing would be extremely difficult if not impossible. In a number of medical centers, it was found that various hospitals of the armed forces, the Veterans Administration and the Public Health Service showed definite lack of integration and waste both of plants and of medical personnel because there was no over-

*Presented at the annual meeting of the Massachusetts Medical Society, Worcester, May 24, 1949.

†Professor of public health practice, Harvard School of Public Health.

all plan for utilization. It was recommended that "hospital care for federal beneficiaries should be planned in relationship to the hospital resources of the country as a whole, not merely through construction of federal hospitals as a class apart."¹ Federal patients requiring hospitalization should be placed in nonfederal hospitals on a reimbursable basis instead of further enlargement of the federal hospital plant. In other words, nonfederal facilities being constructed under the Hill-Burton Act should be co-ordinated with the federal hospital system.

The quality of medical care available to beneficiaries of the federal Government varies greatly depending on which agency provides the service, whether or not facilities operated by this particular agency are readily available, whether sufficient technical personnel is at hand and so forth.

Congress has failed to define clearly its policy regarding beneficiaries of federal medical service. For example, veterans with nonservice-connected disabilities are entitled to hospital care under the vague authorization "if beds are available." As a matter of fact, 100,000 beds have been built to make them available for this group, since Congress has simply not faced the issue squarely. On the other hand, preventive services that might avoid subsequent costly hospitalization cannot be given to veterans without service-connected disability. Care for dependents of Army personnel is based on an authorization sixty years old providing that "whenever practicable" these dependents shall be provided with care. As a matter of fact, some 900,000 dependents of Army personnel are presently considered eligible.

The best possible use has not been made of highly skilled practitioners and personnel available through university medical schools. The Veterans Administration has made an excellent beginning and established a number of hospital programs in conjunction with medical schools, but this is a rather recent development and it certainly is fair to state that in general the objective has been to set up a full-time staff for federal hospitals with relatively little attention to the possibilities of utilizing part-time services from physicians serving the general public.

MAJOR RECOMMENDATIONS

To meet the weaknesses found, a united medical administration is recommended. This would be formed by consolidation of the major activities of the federal Government in medical care, medical research and public health, with an operating division in each of these principal fields. A division of staff services would provide for management, research, control of finance, personnel, supply and so on. Major activities to be included in the united medical administration would be medical care activities of the Veterans Administration, general hospitals and post or station hospitals (except those in isolated areas) of the armed forces within the con-

tinental United States, the entire Public Health Service, nonmilitary hospitals in the Canal Zone and the Food and Drug Administration.

The armed forces medical services would retain all responsibility for activities overseas, for military preventive medicine and for outlying post and station hospitals within the continental United States. Each of the forces would also retain a medical center for training and research. Medical care of Indians and federal prisoners would be provided by agencies presently responsible for these services, but united medical administration personnel would be assigned to work in these agencies. The Soldiers' Home, the Naval Home and health functions incidental to the operation of various federal agencies, such as the Atomic Energy Commission and the Tennessee Valley Authority, would not be included.

At the head of the united medical administration would be the ablest health and medical administrator obtainable. He and his top assistants would be appointed by the President and confirmed by the Senate. A career service for technical personnel would be developed on a basis somewhat similar to that now operating successfully for such personnel in the Veterans Administration. An advisory board to assist the administrator would consist of the Surgeons General of the Army and Navy, the Air Surgeon and the Administrator of Veterans Affairs. Congressional action is necessary to define clearly the beneficiaries entitled to governmental medical care and to prescribe ways in which this care should be made available.

Control of armed forces medical policies should be exercised by the Secretary of Defense. In each geographic area where members of the armed forces and others are operating under military control, responsibility for hospitalization and much of the outpatient care for all United States personnel in the area should be assigned to a single one of the armed forces.

Although there is obviously a need for federal assistance to medical and health education, it is indefinite to the point that a survey is required to determine the exact amount of federal assistance necessary.

"The necessity for medical care which requires heavy expenditures and much personnel, must not be permitted to result in minimizing the even greater importance of controlling disease."² Therefore, research, preventive medicine and public health are given the highest priority in the Commission's report. At numerous points in the report the idea is stressed that only by knowledge and application of new methods of controlling disease can the increasing costs of medical care be reduced.

INDEPENDENT HEALTH AGENCY

The Committee on Medical Services at first worked on the assumption that the Hoover Commission would recommend a combined department

of health, education and security. Later the Commission indicated that such a recommendation might not be made and asked the Committee what its reaction would be to an independent health agency. The suggestion was that such a plan might be preferable to the combined department. The Commission, in its final report, was divided on the question. It was pointed out that in a combined agency, co-ordination of health, education and security would obviously be simpler than in separate departments. The combined agency would meet the Commission's objectives of reducing the number of agencies reporting to the President to a manageable number. The tendency for overemphasis on professionalism would be reduced to a minimum in the combined organization. It was suggested by one member of the Commission that even if a separate agency were established for medical care, the public-health functions should be part of a combined department so that health activities relating primarily to state and local governments could be co-ordinated with similar programs operated by the federal Government in the fields of health, education and welfare. This type of arrangement, however, would separate curative and preventive health activities of the federal Government and would therefore be undesirable.

In an independent agency health functions would be segregated and not subject to irrelevant considerations relating to education and welfare. This might be desirable for certain other departments such as the armed forces, which would use medical services only. Health appropriations could be identified clearly as such. The implementation of special personnel policies considered necessary for the health field might be easier in a separate agency than if health were only one bureau of a combined department. In the separate agency pay and status of the top personnel would doubtless be higher and therefore more attractive than those of a bureau chief and his major subordinates in a combined department. It was suggested that even though a combination might eventually be desirable, the problem of integrating all the medical services to be included in the united health administration was such a great one that even if only as an initial step a separate agency would be desirable.

VALUE OF PREVENTIVE MEDICINE

At many points in its report the Commission and the Committee on Medical Services stressed the importance of preventive medicine. All phases of the health program must receive proper emphasis if the best results are to be obtained. Medical care programs and medical research carried on by the federal Government must be related intimately to activities in public health and preventive medicine. As new procedures are made available by research they must be incorporated promptly into practice. The public must be told what is available and induced to obtain

for themselves the benefits of modern medical science. In this way members of the health team concerned with diagnosis and treatment of disease should be relieved of an increasing part of their heavy burden. With the passage of time it may be that people will more and more come to regard disease as a result of failure to apply available knowledge rather than as the result of bad luck.

At the moment it is extremely difficult to estimate with any accuracy possible savings in the cost of illness that could be accomplished through full use of all present knowledge of disease prevention. Health and productivity are intangible values, and it is unprofitable to attempt complete separation of prevention and treatment since one merges imperceptibly into the other. Incomplete statistics of illness rates also complicate the problem. Some direct costs of illness may be computed fairly satisfactorily, such as doctors' bills, medicines and hospitalization, in addition to wages lost because of illness and potential earning power lost through premature death. However it is difficult to compute the cost to industry of idle machines and impairment of productivity of other workers by absence of the sick man.

As of 1948 expenditures for medical care were estimated at \$8 000 000 000 per year, and the loss in output due to disease and injury estimated at \$27 000 000 000 annually. How much of this amount could be saved if all known preventive measures were applied to the fullest possible extent and if research were supported at the optimum level to make new methods of prevention, health promotion, medical care and rehabilitation available as rapidly as possible? Of course, no one can answer this question. However, the results would undoubtedly be astounding. A few examples of what may be accomplished by preventive measures will give some indication of the results that might be expected.

Industry — Employers report that a first class medical and safety department will reduce occupational disease 63 per cent, absenteeism 30 per cent, compensation cost 29 per cent, and labor turnover by 27 per cent.

Armed Forces — Various types of vaccination, plus sanitation and DDT, made losses due to typhoid fever, small-pox, typhus, cholera, plague, yellow fever and tetanus negligible. Malaria was a minor problem within the U. S. and responded satisfactorily to vigorous control measures in the Pacific. Through x-ray screening at induction centers 150 000 cases of tuberculosis were kept out of the armed forces and the tuberculosis incidence among the forces and among veterans since the war has been only about one tenth that of World War I. Deaths from disease were a much smaller proportion of total deaths than in any previous war, with a 1:16 disease to battle death ratio in World War II, an approximately equal ratio in World War I and a 1:1 ratio in the Spanish War.

Cancer — If all the 334 000 new cancer cases each year had the best modern treatment in states possible with early diagnosis we might anticipate about 200 000 five-year cures contrasted with about 9000 from the average type of treatment given after cancer becomes widespread.

Tuberculosis — Based on 1945 standards the annual cost of tuberculosis to the nation is estimated at \$56 million dollars. If we were willing to spend only \$1 million more each year for ten years it is estimated that tuberculosis

could be so reduced that only 37 million a year would be needed thereafter to keep it under control

Malaria — The estimated 2 million cases a year cost some 500 million dollars. Based on control programs around military areas during World War II, it is stated that with 53 millions spent over seven years malaria could be virtually eradicated so that only a quarter million a year would be needed thereafter to keep it under control

Maternal and Child Health — If the entire country had the infant mortality and maternal mortality rates of our best states, nearly 22,000 infants and 2100 mothers would be saved annually

Life Expectation — At birth, life expectation for white females is now 70.3 years having increased steadily by over 25 years since 1890 due largely to control of communicable diseases and better infant care. However, expectation at age 50 is increasing only slowly because diseases of later life have not yet been greatly affected by preventive measures. Based on experience of other countries, it is not at all unreasonable to hope for three or four additional years expectation at 50

If the 15 major causes of death during the productive period from 20-65 were completely eliminated, 178,500,000 years of productive life would be added for white males alone and life expectancy at 20 increased by 3.95 years

Some of the most important causes of death during this period are definitely amenable to preventive measures now available. A reasonably conservative estimate indicates that of the theoretically possible addition of 3.95 years, 1.95 could be achieved by full application of our present knowledge

SUMMARY

These are but a few examples of what preventive medicine can accomplish. Implementation of the Hoover Commission recommendations would provide a unified service giving proper emphasis to research and preventive medicine as well as to medical care

PROCAINE PENICILLIN G FOR AQUEOUS INJECTION*

A Study of Blood and Urine Levels

MAJOR EDWIN J. PULASKI, M.C., U.S.A.,† AND CAPTAIN JAMES F. CONNELL, JR., M.C., A.U.S.‡

FT. SAM HOUSTON, TEXAS

RECENT developments in penicillin-therapy dosage schedules have resulted in numerous studies dealing with the significance of blood levels. The object of this communication is to report data concerning the blood plasma penicillin levels and urine concentration curves following intramuscular

administration of aqueous solution of procaine penicillin (Crysticillin)§

This procaine salt is relatively insoluble in aqueous solutions and body fluids, and this property forms the basis of a new principle in penicillin administration. It has been demonstrated that the addition of

monstrable levels at twenty-four hours. Our study is essentially a confirmation and extension of these findings.

MATERIALS AND METHODS

Procaine penicillin G (Crysticillin) is prepared for use by suspension of the powder in sterile distilled

water or sterile isotonic solutions of sodium chloride. This suspension has been administered to young male adults in one, two or three injections on a

THE USE OF PSYCHOTHERAPY IN GENERAL PRACTICE*

LEO ALEXANDER, M D †

BOSTON

PSYCHOTHERAPY is part of medical practice. As with any useful medical procedure it should not remain limited to the specialist's office. Like all medical procedures, psychotherapy contains elements of art as well as of science.

In the practice of psychotherapy actions and attitudes are frequently more important than words. Emotionally sick adult people have a good deal in common with children, in particular the fact that their complaints and abnormal actions frequently express their feelings and problems in a symbolic rather than a direct manner, that they both frequently distrust words, that they learn more from example and the opportunity to identify themselves with good leadership than from precept, and that they relate themselves to the world more through emotional experience than according to instruction. Thus, how the doctor acts toward the patient, how he listens to him and how he speaks to him is often more important than what he tells the patient. It is frequently of greater value to offer new good interpersonal experiences than new thought content, although both are inextricably interwoven.

In its most elemental and nonverbal form, psychotherapy can be carried out successfully even on animals.^{1, 2} It is obvious that in the treatment of animals attitudes and actions play the main part, since animals do not understand words. But the ability to influence animals or human beings by attitudes and actions is the most important natural gift of the psychotherapist.

If I were asked to devise a screening test by which candidates gifted for psychotherapeutic work could be discovered, I should say that the person most likely to become a good psychotherapist was the type of person to whom stray dogs take easily, who could effectively gain the confidence of beaten dogs or who could easily ride an anxious horse that was sensitive to the bit and that customarily shied at the slightest provocation. I should place much more emphasis upon these faculties and attitudes, which are inherent as well as acquired than upon theoretic psychodynamic knowledge. The psychotherapist must constantly keep in mind that his actions and his attitudes are at least as important as his words.

Once the principle has been understood the technics can be learned. They fall essentially into

the following groups: supportive treatment, ventilation, shift of emphasis, interpretation, and reassurance. It is of particular importance, of course, to know the limits of these various forms of psychotherapy and to know when to add other methods such as medicinal forms of treatment or when to refer patients to a specialist for more intensive abreactive or interpretive psychotherapy or for the various forms of shock treatment, such as electric shock or insulin coma treatment³ to modify successfully abnormal emotional or mental states.

MAIN PSYCHOTHERAPEUTIC TECHNIQS

Supportive Treatment

The main element of supportive treatment is the doctor's attitude. Irrespective of whether the patient comes to him with a physical ailment or with a neuropsychiatric disease manifested by physical complaints, it is of fundamental importance that the doctor listen to the complaint, take it seriously and subject the patient to a thorough physical examination. The thoroughness of an examination frequently determines the success of supportive treatment. The effect of such treatment is, of course, enhanced by the doctor's reputation in the community — by his standing as a professional man and citizen. Both a doctor's reputation and his thoroughness enhance each other, conversely, it can sometimes be disastrous if a well qualified and highly respected physician takes the complaint of the patient lightly and because of his initial impression and shortage of time subjects him to a hurried and superficial examination. This can increase the feeling of rejection at the hands of life, which may be the main factor in the neurosis of an unsuccessful man or a rejected, unloved woman or child. The doctor must give, by his attitude and actions, the assurance to the patient that he cares for him, that he is interested in him and that he is eager to help him. There is an old saying that "a specialist is a man who does a rectal examination." I should like to paraphrase this and say that a psychotherapist is a physician who takes a complete and thorough history and who does a complete and thorough physical examination.

The degree to which such an attitude is psychotherapeutic was recently brought home to me by a patient who consulted me in a state of severe anxiety. This forty-six-year-old man complained of extreme nervousness, sweating pains throughout all bones of his body and attacks of weakness lasting several days at a time. He was very anxious and tense,

Supportive Treatment

The main element of supportive treatment is the doctor's attitude. Irrespective of whether the patient comes to him with a physical ailment or with a neuropsychiatric disease manifested by physical complaints, it is of fundamental importance that the doctor listen to the complaint, take it seriously and subject the patient to a thorough physical examination. The thoroughness of an examination frequently determines the success of supportive treatment. The effect of such treatment is, of course, enhanced by the doctor's reputation in the community — by his standing as a professional man and citizen. Both a doctor's reputation and his thoroughness enhance each other, conversely, it can sometimes be disastrous if a well qualified and highly respected physician takes the complaint of the patient lightly and because of his initial impression and shortage of time subjects him to a hurried and superficial examination. This can increase the feeling of rejection at the hands of life, which may be the main factor in the neurosis of an unsuccessful man or a rejected, unloved woman or child. The doctor must give, by his attitude and actions, the assurance to the patient that he cares for him, that he is interested in him and that he is eager to help him. There is an old saying that "a specialist is a man who does a rectal examination." I should like to paraphrase this and say that a psychotherapist is a physician who takes a complete and thorough history and who does a complete and thorough physical examination.

The degree to which such an attitude is psychotherapeutic was recently brought home to me by a patient who consulted me in a state of severe anxiety. This forty-six-year-old man complained of extreme nervousness, sweating, pains throughout all bones of his body and attacks of weakness lasting several days at a time. He was very anxious and tense,

*Presented at the annual meeting of the Massachusetts Medical Society May 26 1949.

†Instructor in psychiatry Tufts College Medical School director Neurobiologic Unit Division of Psychiatric Research Boston State Hospital.

and he was sweating profusely. He sat with his arms tightly pressed to his body. On the examining table his muscles seemed to be in a state of tension, and he had difficulty in relaxing them. He showed a markedly increased startle-pattern response, whereas all spontaneous motor activity was greatly reduced. It may be that I subjected this man to a particularly thorough neurologic examination because I wanted to be sure to find or rule out the existence of an organic neurologic condition, since he had suffered a blast injury, but the inadvertent psychotherapeutic effect of this detailed and painstaking examination was both surprising and delightful. As the examination progressed the patient gradually relaxed, and after it was over he was not only at ease but also cheerful and smiling. He departed in a state of apparent well-being. Without any direct psychotherapy, the acute anxiety state, obviously caused by the fear of having been seriously injured, melted under the impact of a thorough, sympathetic, careful examination, which was terminated by an encouragingly worded verdict of the finding of physical well-being. If this verdict had been rendered after a less painstaking examination, it might very well have aroused resentment and antagonism, followed by a build-up of anxiety and further discouragement. In other acute situational anxiety reactions, regardless of whether they express themselves in fear of injury by a serious accident or a fear of heart disease or any other physical ailment, the verdict of physical health will be acceptable to the patients only if they have been subjected to an examination that they accept as being of sufficient thoroughness, and the doctor must express by his attitude the fact that he has an open mind and that he is interested in finding out the truth.

Part of psychotherapy is teaching, and the most effective way of teaching is by example. If the physician wishes the patient to have an open mind and accept the truth, the patient must first be shown that the physician has an open mind and is interested in the truth himself. In a good relation the patient will unconsciously imitate the physician's own attitude. The arousal of mimesis is indeed the most important instrument of successful teaching, as well as of successful psychotherapy.

Of course, such reassurance cannot overcome a severe, deeply ingrained anxiety neurosis or a pre-psychotic panic, but an attitude of a wide-open mind and thoroughness will be helpful even in those conditions, although it may be then wise to withhold reassurance and interpretation until the patient himself is ready to accept them. Again, it is important to know one's limits. Unless the physician is very sure that the patient is ready to accept reassurance and interpretation, both of which must be used with great caution, it is much better to help the patient to stumble upon the solution by merely helping him with an attitude of thoroughness, open-mindedness and interest in the true state

of his health. It is important to realize that reassurance is not always real support. The anxious patient who believes that he is dangerously sick will more frequently regard reassurance as a brush-off and a lack of real interest on the part of the physician.

I once treated a young woman with a severe phobic state that had many features of an early schizophrenic psychosis with obsessive features. Nevertheless there was a great deal of meaningful material that prompted me to go on with psychotherapy. This patient had been to many doctors, including psychiatrists, and had left them all after a few visits. After a long course of treatment with many ups and downs, she finally became well fifteen months later. I then asked her, as I frequently do of recovered patients, what in her opinion was the most decisive therapeutic act to which she ascribed her recovery. Her answer was as follows:

When I went to you for the first time I did not like you, and I almost did not want to come back. When I came the second time I asked you a question — namely, whether I was actually out of my mind (I had the fear that I was going crazy or had actually gone crazy). When I asked you that you said, "I don't know. We have to find out first and then do the right thing about it." That gave me confidence in you. All the other doctors I had been to told me that I wasn't out of my mind and that I wasn't going to lose my mind, and I thought that they didn't understand me or they didn't tell me the truth. When you told me that you didn't know, I knew that I could have confidence in you, that you were honest and that you would always tell me the truth. From then on I kept coming back and I got well.

The answer I gave this patient had actually been the truth. After a number of interviews and equivocal tests I was not quite sure whether this was not an acute schizophrenic development that would be better treated with shock or insulin. The weight of evidence finally was in favor of a condition considered modifiable by psychotherapy, which turned out to be effective after some time. I knew it was the ring of truth in my statement that carried the weight. It is essential to realize that emotionally sick people, like children, have an uncanny sense of truth. This is particularly important in dealing with children. The ability of children to look through and size up their parents and others close to them is frequently equal to that of trained psychologists and psychiatrists. True supportive therapy can therefore never be given without the solid foundation of conviction of truth in what the therapist is saying. In supportive treatment one must definitely show that one is on the side of the patient in his battle with the world.

Ventilation

Next in importance to the supportive attitude is that of giving the patients the full opportunity and the setting of understanding approval in which they can freely ventilate their stresses and emotions. Once the patient is started in successful ventila-

tion, the physician should interrupt the patient as little as possible, but merely sit there with the understanding and encouraging smile of the statue of a wise Buddha. This technic is particularly helpful in certain cases of anxiety hysteria as well as in the anxiety states of the older age groups, especially those with hypertension. A good example of the former type is the case of a young married woman, aged thirty-five years, who came to my office in a state of marked distress and agitation, complaining of severe and persistent pain in her left cheek. She held her hand pressed against her cheek, stating that as soon as she released the pressure of her hand the pulsating became unbearable. This constant, throbbing pain had been present for three years. She had consulted a good many doctors, including two neurosurgeons and several dentists, about her complaint. Two weeks before referral to me, the patient went back to her first dentist, who took out an additional tooth (several had previously been extracted), which brought about no improvement. She was then referred to an otolaryngologist for investigation of her ears, nose and throat. He found no physical abnormalities that could be causing her complaint, and referred her for neuropsychiatric examination. She stated that this pain might be due to "something terrible" she had done in early life and that she had a guilty conscience that "bangs in the back of my mind." She then began to tell the grim history of her life. In the psychotherapeutic discussions with this patient I completely refrained from giving any interpretation, but instead merely helped her by occasional questioning to find the meaning of her symptoms herself. After the sixth interview her pain was gone, and recurred later only on two occasions for brief and meaningful periods after the twelfth interview. It remained absent after the thirteenth interview and did not recur at any time within three years of the sixteenth and final psychotherapeutic session.

An equally striking reaction to purely ventilative treatment occurred in a forty-six-year-old man who suffered from a chronic anxiety state with mild hypertension and symptomatic alcoholism. He had previously been refused insurance because of hypertension. When I first examined him, his blood pressure was 175 systolic, 80 diastolic. His wife had been on the verge of leaving him because of his drinking. Psychotherapy in this patient remained entirely ventilative in character. It appeared that he derived particular benefit from the opportunity to "blow off steam" regarding his resentment against his employers and business associates. There was remarkable gradual diminution of his anxiety as well as his hypertension. After three months of treatment his anxiety became sufficiently diminished that he felt able, without, of course, any implication of advice on my part, to take a step that he had wanted to take for many

years but had never quite dared to — namely to resign from his organization and to go into business for himself. Subsequently, his blood-pressure readings remained consistently normal, 130 systolic, 65 diastolic. His symptomatic indulgence in alcoholic beverages likewise improved, and he remained well and congenial with his family.

It is frequently observed that when ventilation proceeds on a purely intellectual level, without associated emotional expression, the therapeutic benefit is minimal or absent. The patients may tell their story, and at the end they may say, "This is my story, Doctor, but what does telling it do for me? I still feel the same way." It is then that one must bring about real emotional participation, an emotional reliving of the stress situation, for which the word *abreaction* has come into vogue, which literally means to react off or to "blow off steam."

I believe that the physiologic result of *abreaction* as a form of excitation can best be understood in Pavlovian terms. It is conceivable that the intense excitation of neurons associated with electric shock may be the extreme physical variant of the same principle. It appears that the bringing about of excitation, quite apart from the interpretation and working out of the emotional material, has in itself a wholesome effect, irrespective of whether the excitation was produced by the reliving of a recent crushing-threatening episode, by the bringing out of old resentments by verbalization, by reliving of emotional conflict, by the participation in exciting ritual or by the touching off of extreme excitation of the entire nervous system by an electric stimulus.

It must not be forgotten, however, that in spite of the strong physiologic components of the experience, the reliving and working out and the psychotherapeutic guidance and other forms of psychotherapy and understanding are of the greatest value. In spite of all the lip service given to the unity of mind and body, many physicians find it difficult to accept the fact that there is no separation of the psychologic and the physical aspects of treatments. Both should be utilized to the fullest for the recovery of the patient.

The more specifically psychotherapeutic technics consist of those which promote insight and which have to do with interpretation either directly or indirectly. The indirect method is preferable particularly for the beginner and in the beginning of psychotherapy. It is very important not to overwhelm the patient with interpretation and thereby to build up his defenses and resistances, but it is essential to feel out the patient before attempting to do so. It must be remembered that the scaling of strong defenses is a risky task, in psychotherapy as well as in war. The wise general or the wise psychotherapist will prefer a flanking movement, in the long run it will save time and risk.

Shift of Emphasis

The "flanking movement" that should precede direct interpretation and frequently is sufficient to take the place of direct interpretation is the shift of emphasis. By this I mean the subtle shifting of emphasis from the complaint or the apparent conflict to the more important material that the patient may have presented quite inadvertently without having been consciously aware of its import in relation to his complaint. The advantage of this technic is that it does not arouse antagonism and resistance. It is wise to take as a starting point something that the patient himself has told one.

A recent example is afforded by the case of a fifty-year-old man who reported to the outpatient clinic with a complaint of severe pain throughout the left side of the chest, for which he had first consulted the heart clinic, which referred him for neuropsychiatric consultation for the differential diagnosis of intercostal neuralgia or psychoneurosis. As frequently happens, the patient gave his problem away with the first sentence he spoke when he introduced himself. He said, "I want to explain to you why I come to this out-patient clinic instead of consulting a private doctor. I am a pharmacist, but I can't work in my line here in Massachusetts because my degree is not recognized here, but my wife wants us to live here because of our son. Therefore I have to work as a storeroom clerk and can hardly make enough money to get by." He then described with great vividness the pains in the left side of his chest. He felt deeply distressed and alarmed about them, and they were a very profound reality to him. Careful examination in addition to the clinical and laboratory tests done before convinced me that this patient was not suffering from organic disease. Furthermore, his marked state of anxiety and depression was positive evidence of an emotionally determined illness. On the other hand I believed that he would not take well to direct interpretation. At the conclusion of the examination, which I had carried out with great thoroughness, I imperceptibly shifted from the discussion of his complaints to that of his life situation. Very soon the patient was well in the process of discussing his impasse and obviously eager for what suggestions would be made. I dropped the hint that many illnesses improve provided the patient is happy or finds a way of being happy. Before long we were discussing ways of improving his life situation. It turned out that a compromise was feasible. A neighboring state was chosen where he could work in his own field and yet be sufficiently near his son to suit his wife. The mere possibility of doing something about his problem and the support implied in the assumption that he had a right to consider his own occupational happiness relieved him. In the course of readjustment of his life situation the pain vanished, and the danger of antagoniz-

ing the patient by the direct proffering of insight was avoided.

Interpretation

Although I refer here to interpretation of emotional illness, I believe it also holds true for physical illness that interpretation of the illness to the patient is an important part of medical management of the sick person. Interpretation is the most difficult part of psychotherapy, it requires the greatest amount of skill, tact and timing. It should not be attempted until one is very sure of one's ground and after one has established a good relation with the patient. The results are seldom as dramatic as those portrayed in the motion pictures. It is rather a slow process of understanding, and results from a continued co-operative effort of doctor and patient. Nevertheless, there are occasional cases in which a dramatic denouement may be achieved by a well timed interpretation for which the patient is ready. The most important thing is to interpret in terms acceptable to the patient. A genuine understanding of the patient is a prerequisite for such a procedure to be carried out successfully.

Even in insight-promoting treatment, actions and attitudes are an important instrument of therapy. The actions and attitudes that have been found beneficial and helpful on the basis of psychodynamic understanding are remarkably similar, even identical, with those derived from true religious attitudes. F. Alexander and M. T. French⁴ pointed out that the priest in Victor Hugo's novel *Les Misérables*, written as long ago as 1862, reformed the hero of the story, Jean Valjean, who had tried to rob him, by treating him with attitudes and acts of unexpected kindness, which constituted a masterpiece of brief psychotherapy. It is of fundamental importance that age-old spiritual insight and modern psychodynamic insight have led to the same conclusion: that certain thieves are deprived people who must first be given to before they can be reformed. It is likewise of interest in this connection that modern psychotherapy has rediscovered the value of love, in the spiritual sense of the word, as a therapeutic force.

Like all therapy that offers or suggests insight, even actions and attitudes if they serve that end are resisted by defenses to which the patient will cling until he becomes free enough to give them up. Thus, Jean Valjean's first reaction to the priest's kindness was one of a temporary recrudescence of his hostile behavior before he became able to give it up altogether. F. Alexander and French point out that even in this respect Valjean's reform conformed to the familiar rebounding pattern of response of a symptom or neurotic attitude to psychotherapy. This pattern also conforms to Pavlov's laws of the higher nervous activity of the cortex. In Pavlovian terms this initial negative reaction could be described as negative induction by a new

conditioned stimulus followed by positive induction that reinforces the stimulus sufficiently to allow it to irradiate. It appears that psychotherapy is a real force conforming to spiritual as well as to natural laws.

Reassurance

It is essential for reassurance that the patient believe that the doctor is truthful and that he has been sufficiently thorough to know whereof he speaks. In actual mental illnesses or severe neuroses, reassurance is of only secondary importance apart from its use as an adjunct to general supportive technic. Reassurance, however, is of great importance as a preventive measure. Irrespective of whether or not a physician chooses to treat overt neuropsychiatric conditions in his practice, there is one field in which he must do psychotherapy — that is, whenever he deals with chronic or incurable physical illnesses. In these conditions a great deal depends on the doctor's psychotherapeutic handling of the problem. The existence of such an illness constitutes severe neurosis-producing stress, and this superimposed neurosis or depression frequently makes the difference between an invalid and a reasonably active and well adjusted person. The way in which the physician handles such a problem may prevent, control or, on the other hand, sometimes even precipitate the superimposed neurosis. Thorough, warm understanding of the patient with a knowledge of his emotional needs will do a great deal to prevent superimposed neurosis in such cases. The problem begins with the way in which the diagnosis should be told to the patient. I personally favor giving the patient the true diagnosis, but in encouraging terms. Not telling the diagnosis sometimes makes the patients fear a worse possibility than even that which the well meaning physician has withheld. Another important point is to maintain in the patient a feeling of control — a feeling that he can do something for himself. Abandonment to fate constitutes extreme stress that few people, not even some of the most sturdy combat personnel in war, can take.

One should therefore never tell the patient "There is nothing I can do for you," without at least offering a program of things that he could do for himself and continuing to show a helpful interest. All too frequently such patients are abandoned to their own devices. The rationalization for doing so is usually a perfectly ethical one. The real motive, however, is more complicated. The chronically or incurably ill patient represents a tremendous challenge to the physician's opinion of his own healing abilities, which will frequently put him on the defensive, especially when the patient on his part enhances this challenge by openly hostile, demanding or critical attitudes. It is therefore understandable that in such a setting the doctor, espe-

cially when he is sensitive to criticism and hostility, may tell the patient that he can do nothing for him in such a way as to imply "There is nothing anybody can do for you," which to the patient means complete rejection and abandonment. It must never be forgotten that a principal function of the physician is to give hope to the patient and to relieve his relatives of responsibility by not dodging any responsibility himself.

It is also important to guard against an attitude of rejection in referring mental patients to a psychiatrist. The manner of the referral frequently determines success or failure of the patient's first contact with the psychiatrist and conditions his readiness to accept treatment. If the physician refers the patient with an attitude of rejection and detached disinterestedness in his problem, which to the patient implies "You are crazy, and you ought to go to a psychiatrist," he will go to the psychiatrist with a chip on his shoulder and co-operation will be difficult to obtain. If, however, the physician refers the patient to the psychiatrist in the same manner in which he would refer a patient to any other specialist, saying, for instance, "I want you to see my friend Dr. so and so, he is a specialist in this field, I am sure he will help you and I shall keep in close touch with him," the patient and his relatives will come prepared to have confidence and co-operation will result as a matter of course in a smooth and automatic manner.

CONCLUSION

I should like to conclude this paper with a few do's and don't's in the use of psychotherapy in office practice. In general one cannot go wrong with a warm supporting attitude, and in offering the patient opportunity for ventilation. If this ventilation should be associated with a marked emotional abreaction, the objective, supporting attitude must be maintained in the face of it, even if this abreaction should include the expression of hostility toward the physician. One should not interpret unless one is really sure of the ground — much damage can be done by novices.

If the patient improves only at the price of too much dependence on the therapist, or if he becomes dependent without improving, he should be referred to a person with more skill and experience in the field of psychiatry. It should be remembered that dependence is regression into an infantile state. Although the regression is sometimes necessary as a transitory phase during treatment, and frequently is undesirable even then, one must ultimately wean the patient and help him to mature. A physician of my acquaintance who rather prides himself on his self-taught skill in his psychotherapeutic management of neurotic patients told me once as a proof of his accomplishments that his cured neurotic patients retained so much confidence in him that for

years after treatment they would make no major decision without asking his advice, even in entirely nonmedical matters. To me this sounded as if a surgeon were taking pride in the fact that his patients were letting him dress their still-draining incisions for years after each operation. The primary goal must be kept firmly in mind to help patients to achieve health, happiness, maturity and independence. In every psychotherapy there comes the time when one must throw the ball of responsibility

determinedly to the patient, and trust him to carry it.

SYPHILITIC AORTITIS WITH OBSTRUCTION OF MULTIPLE AORTIC OSTIA*

WILEY F BARKER, M D †

BOSTON

UNTREATED or inadequately treated late syphilis is no longer so frequently seen by the average physician, and its exotic complications are becoming curiosities. The following case presents one of the more unusual cardiovascular complications.

CASE REPORT

S L (P B B H 7A850), a 52-year-old shipping clerk, was admitted to the Peter Bent Brigham Hospital on March 15, 1948, complaining of severe pain in the anterior part of the chest radiating down the left arm. This symptom had been present, especially on exertion, for about 10 months. The initial episode of pain had occurred while he was walking one evening, a sense of constriction in the chest and a pain in the left arm developed. After resting for several minutes he had been able to return home. Other attacks following a similar pattern became more severe and more frequent. Four months before admission he was admitted to another hospital for diagnostic studies.

Physical examination had revealed a markedly apprehensive man. There was a barely palpable radial pulse on the right, the left radial pulse was weak but palpable. The right carotid pulse was scarcely palpable, but the left carotid pulsation was full and bounding. There was no evidence of cardiac enlargement or other cardiovascular defect.

A positive serologic test for syphilis was obtained. Other blood examinations were within normal limits. An electrocardiogram was interpreted as showing myocardial changes, with a rate of 72 and nodal rhythm. The PR interval was 0.09 to 0.12 second, and the QRS complex was normal. RT was depressed in Lead I, V_4 and V_5 . The P waves were inverted in Lead 2 and 3 and upright in Lead 4. The T waves were diphasic in Lead 1 and V_5 , upright in Lead 2 and 3 and low in Lead V_4 .

The patient was discharged to the care of his physician with a diagnosis of anxiety state, angina pectoris, syphilis and a suspected congenital anomaly of the great vessels. Six million units of penicillin in oil was administered at home over the course of 10 days. There was no Jarisch-Herxheimer reaction and no subsequent reversal of the blood Hinton reaction to negative.

Symptoms continued, and the patient was given various medications including opiates, salicylates, Demerol, chloral hydrate and barbiturates without significant relief from pain. Nitroglycerin afforded only brief palliation. The severity and frequency of the attacks progressed until 4 days before admission, when the pain and sense of constriction became unremitting, with continued reference of pain down the arm, unrelieved by nitroglycerin. He had had no marked dyspnea,

orthopnea, ankle edema or cyanosis, but he had complained of profuse sweating and a sense of impending disaster. He was referred to this hospital by his physician.

Further past history was limited by the patient's inability to answer all questions. He had had no other significant illnesses and no operations. He denied any venereal disease other than gonococcal urethritis as a young man. He stated that as far back as he could remember he had had a small pulse in his left arm and an almost impalpable pulse in his right arm.

The patient was apprehensive and ashen faced, sweating profusely, and complaining of pain in the chest and left arm. The pupils were normal. No abnormalities of the nervous system were demonstrable. The chest was clear on the left, but on the right there was basal dullness, with diminution of breath sounds, bronchial breathing and moist rales. The right carotid pulsation was absent, a moderate pulsation was present in the left carotid. No pulse could be detected in the radial vessels on either side. Femoral and dorsalis pedis pulses were palpable but weak. The heart was not enlarged, the sounds were normal and without murmurs or friction rub. The abdomen was slightly distended, without fluid, and the liver edge was palpable but nontender three fingerbreadths below the costal margin. There was no abdominal tenderness.

The temperature was 101.8°F (by rectum), the pulse 104, and the respirations 30. The blood pressure was 0 in the arms and 100 systolic in the legs as determined by palpation of the dorsalis pedis.

Films of the chest taken at the bedside revealed a high diaphragm and a fairly marked degree of pulmonary congestion and edema. The heart appeared slightly enlarged to the right and to the left, although the right border could not be seen in its entirety. The aorta did not appear widened.

The urine was acid, with a specific gravity of 1.033. No albumin was found, but there was a + test for sugar and acetone. Rare red and white cells and hyaline casts were reported in the spun sediment. The hemoglobin was 15 gm per 100 cc, and the hematocrit 44 per cent. The corrected sedimentation rate was 21 mm per hour (normal, 15 mm). The white-cell count was 19,650, with 68 per cent neutrophils, 17 per cent band forms, 11 per cent lymphocytes and 4 per cent monocytes.

Electrocardiograms revealed an abnormal form of ventricular complex — the ST segment was depressed in Lead I and markedly depressed in Lead 2 and 3, the T wave was inverted in Lead 3. The unipolar limb leads showed an elevated ST segment, late inversion of the T wave in Lead AVR, elevated ST segment in Lead V_1 to V_3 and depressed ST segment in Lead V_4 to V_6 . These tracings were considered suggestive of infarction of the anterolateral aspect of the left ventricle, with subendocardial extension.

Three hours after admission the heart suddenly stopped, with continuation of respiratory movements for a few cycles. The diagnoses were coronary thrombosis with myocardial infarction, syphilis with suspected aortitis involving the coronary ostia, congenital anomaly of the aorta and possible dissecting aneurysm.

*From the Department of Pathology, Peter Bent Brigham Hospital.

†Graduate assistant in pathology, Peter Bent Brigham Hospital.

At post-mortem examination, performed 3 hours after death, the body was that of a well developed and well nourished man. There was no peripheral edema. The abdominal cavity contained no free fluid. The liver weighed 2080 gm and was severely congested. The remainder of the gastrointestinal and genitourinary systems was normal.

There was bilateral hydrothorax, with 500 cc of clear, straw-colored fluid in the right pleural cavity and 350 cc in the left. There was no undue fluid in the pericardial cavity.

The heart weighed 380 gm and was not enlarged. The pericardium was normal. The right ventricular myocardium measured 0.3 cm, and the left ventricular myocardium 1.4 cm in thickness. There was a narrow layer of subendocardial infarction measuring 0.3 cm in thickness encircling the entire left ventricular cavity, with maximal changes anteriorly at a point midway between the base and the apex. The auricles were grossly normal. There was no evidence of valvular disease. The aortic ring showed no dilatation and no separation.

FIGURE 1 Longitudinal Section of the Aortic Arch and Its Branches, Showing Syphilitic Endarteritis

tion at the commissures. The measurements were as follows: tricuspid valve, 12 cm; pulmonary valve, 7.5 cm; mitral valve, 11 cm; and aortic valve, 6 cm.

The coronary arteries were patent throughout their course in the myocardium. At their ostia, however, there was marked thickening of the intima, which had almost obliterated the coronary orifice. At no other point in the course of the main coronary vessels and their main branches was there encroachment upon the lumen, although several small, yellowish atheromatous plaques were seen. The anatomic distribution and the origin of the arteries were normal.

The aorta arose from the heart in the usual manner and pursued a normal course throughout the chest. At the arch the innominate artery and the right common carotid artery arose in close proximity from the apex of a small, shallow outpouching of the superior surface of the arch, which measured 3.5 by 2.5 cm and was 0.7 cm in depth. The left subclavian artery arose from its normal position. Innumerable yellow plaques of atheroma were present from the level of the innominate artery down to the renal arteries. Most of these plaques were slightly elevated but intact; a few, however, were ulcerated. Between the atheromatous plaques in the ascending and descending aorta there was longitudinal wrinkling of the intima in a characteristic "tree-bark" pattern. The wall of the aorta was thickened except for the small outpouching described above and for a small disk-shaped area, 0.8 cm in diameter, in the mid-thoracic aorta where there was marked thinning. It was believed that the origin of the common carotid artery from the apex of the small aneurysmal pouch constituted an anomalous placement of this vessel.

The proximal portion of the lumen of the innominate artery was completely occluded by a smooth, adherent, pinkish-gray tissue. This occluding mass began about 0.5 cm from the orifice of the vessel and extended along its course for 1 cm. The distal surface of this obstruction was composed of two leaf-like cusps with a concavity directed distally (Fig. 1). Distal to this obstruction the vessel was patent, and bifurcated within 2 cm into normal common carotid and subclavian arteries, which followed normal paths into the root of the neck.

The orifice of the left common carotid artery was normal except for its displacement to the right, and for the fact that it was dilated, measuring 1 cm in diameter. It crossed the mediastinum and ascended into the neck in a normal position.

The left subclavian artery was markedly narrowed near its orifice by a valve-like piece of pinkish-gray tissue, similar to that obstructing the innominate artery, leaving a lumen less than 0.3 cm in diameter. The distal course and distribution of the left subclavian were normal. The superior and inferior thyroid arteries were greatly dilated and tortuous, measuring 0.3 cm in diameter.

The lungs showed some basal congestion. The principal microscopic findings of interest were limited to the heart and great vessels. The changes in the heart were

FIGURE 2 Section of the Innominate Artery, Showing Obliteration of the Lumen by the Intimal Proliferation and the Destruction of the Media (Elastic-Tissue Stain)

confined to the inner fourth of the wall of the left ventricle and were seen maximally in the interventricular septum, anterior left ventricle and lateral left ventricular wall. In this region there was an ischemic necrosis of the muscle fibers. There was disappearance and fragmentation of the nuclei in this zone. Minimal numbers of polymorphonuclear, lymphocytic and mononuclear cells were seen between the fibers. This was interpreted as a myocardial infarction of less than 4 days' duration. The remaining myocardium showed an irregularly

years after treatment they would make no major decision without asking his advice, even in entirely nonmedical matters. To me this sounded as if a surgeon were taking pride in the fact that his patients were letting him dress their still-draining incisions for years after each operation. The primary goal must be kept firmly in mind to help patients to achieve health, happiness, maturity and independence. In every psychotherapy there comes the time when one must throw the ball of responsibility

determinedly to the patient, and trust him to carry it.

UNTREATED or inadequately treated late syphilis is no longer so frequently seen by the average physician, and its exotic complications are becoming curiosities. The following case presents one of the more unusual cardiovascular complications.

CASE REPORT

S L (P B B H 7A850), a 52-year-old shipping clerk, was admitted to the Peter Bent Brigham Hospital on March 15, 1948, complaining of severe pain in the anterior part of the chest radiating down the left arm. This symptom had been present, especially on exertion, for about 10 months. The initial episode of pain had occurred while he was walking one evening, a sense of constriction in the chest and a pain in the left arm developed. After resting for several minutes he had been able to return home. Other attacks following a similar pattern became more severe and more frequent. Four months before admission he was admitted to another hospital for diagnostic studies.

Physical examination had revealed a markedly apprehensive man. There was a barely palpable radial pulse on the right, the left radial pulse was weak but palpable. The right carotid pulse was scarcely palpable, but the left carotid pulsation was full and bounding. There was no evidence of cardiac enlargement or other cardiovascular defect.

A positive serologic test for syphilis was obtained. Other blood examinations were within normal limits. An electrocardiogram was interpreted as showing myocardial changes, with a rate of 72 and nodal rhythm. The PR interval was 0.09 to 0.12 second, and the QRS complex was normal. RT was depressed in Lead I, V₄ and V₆. The P waves were inverted in Lead 2 and 3 and upright in Lead 4. The T waves were diphasic in Lead 1 and V₆, upright in Lead 2 and 3 and low in Lead V₄.

The patient was discharged to the care of his physician with a diagnosis of anxiety state, angina pectoris, syphilis and a suspected congenital anomaly of the great vessels. Six million units of penicillin in oil was administered at home over the course of 10 days. There was no Jarisch-Herxheimer reaction and no subsequent reversal of the blood Hinton reaction to negative.

Symptoms continued, and the patient was given various medications including opiates, salicylates, Demerol, chloral hydrate and barbiturates without significant relief from pain. Nitroglycerin afforded only brief palliation. The severity and frequency of the attacks progressed until 4 days before admission, when the pain and sense of constriction became unremitting, with continued reference of pain down the arm, unrelieved by nitroglycerin. He had had no marked dyspnea,

orthopnea, ankle edema or cyanosis, but he had complained of profuse sweating and a sense of impending disaster. He was referred to this hospital by his physician.

Further past history was limited by the patient's inability to answer all questions. He had had no other significant illnesses and no operations. He denied any venereal disease other than gonococcal urethritis as a young man. He stated that as far back as he could remember he had had a small pulse in his left arm and an almost impalpable pulse in his right arm.

The patient was apprehensive and ashen faced, sweating profusely, and complaining of pain in the chest and left arm. The pupils were normal. No abnormalities of the nervous system were demonstrable. The chest was clear on the left, but on the right there was basal dullness, with diminution of breath sounds, bronchial breathing and moist rales. The right carotid pulsation was absent, a moderate pulsation was present in the left carotid. No pulse could be detected in the radial vessels on either side. Femoral and dorsalis-pedis pulses were palpable but weak. The heart was not enlarged, the sounds were normal and without murmurs or friction rub. The abdomen was slightly distended, without fluid, and the liver edge was palpable but nontender three fingerbreadths below the costal margin. There was no abdominal tenderness.

The temperature was 101.8°F (by rectum), the pulse 104, and the respirations 30. The blood pressure was 0 in the arms and 100 systolic in the legs as determined by palpation of the dorsalis pedis.

Films of the chest taken at the bedside revealed a high diaphragm and a fairly marked degree of pulmonary congestion and edema. The heart appeared slightly enlarged to the right and to the left, although the right border could not be seen in its entirety. The aorta did not appear widened.

The urine was acid, with a specific gravity of 1.033. No albumin was found, but there was a + test for sugar and acetone. Rare red and white cells and hyaline casts were reported in the spun sediment. The hemoglobin was 15 gm per 100 cc, and the hematocrit 44 per cent. The corrected sedimentation rate was 21 mm per hour (normal, 15 mm). The white-cell count was 19,650, with 68 per cent neutrophils, 17 per cent band forms, 11 per cent lymphocytes and 4 per cent monocytes.

Electrocardiograms revealed an abnormal form of ventricular complex — the ST segment was depressed in Lead I and markedly depressed in Lead 2 and 3, the T wave was inverted in Lead 3. The unipolar limb leads showed an elevated ST segment, late inversion of the T wave in Lead AVR, elevated ST segment in Lead V₁ to V₃ and depressed ST segment in Lead V₄ to V₆. These tracings were considered suggestive of infarction of the anterolateral aspect of the left ventricle, with subendocardial extension.

Three hours after admission the heart suddenly stopped, with continuation of respiratory movements for a few cycles. The diagnoses were coronary thrombosis with myocardial infarction, syphilis with suspected aortitis involving the coronary ostia, congenital anomaly of the aorta and possible dissecting aneurysm.

*From the Department of Pathology, Peter Bent Brigham Hospital.

†Graduate assistant in pathology, Peter Bent Brigham Hospital.

of a congenital defect, the presumptive explanation is that the obliteration of the great vessels had occurred early in the course of the disease when the patient was still a young man

SUMMARY

A case of syphilitic aortitis and endarteritis in which there was obliteration of the lumen of the innominate artery, partial obstruction to the lumen of the left subclavian artery and almost complete occlusion of the coronary ostia is reported. The patient pursued a steadily downhill course to die of myocardial infarction without actual coronary thrombosis, ten months after the onset of symptoms, and in spite of antisyphilitic therapy with penicillin.

The diagnosis of coronary-ostia disease should be more readily suspected when, in association with electrocardiographic changes of "global ischemia," there is evidence of other ostial obstruction, with or without a demonstrable aortic aneurysm. The current relative infrequency of late cardiovascular

manifestations of syphilis renders them nonetheless important.

PUNCH LIVER BIOPSY IN THE DIAGNOSIS OF MILIARY TUBERCULOSIS

Report of a Case

CHARLES G. CRADDOCK, M.D.,* AND H. C. MEREDITH, JR., M.D.†

CHARLOTTESVILLE, VIRGINIA

SINCE it is often difficult to substantiate a suspected diagnosis of miliary tuberculosis, an additional practical diagnostic procedure would be of value. As it is well known that miliary tubercles are scattered throughout the liver in this disease,¹⁻³ histologic study of a specimen of liver tissue would be of unquestioned value in confirming a clinical impression. In recent years punch liver biopsy has been established as a simple, practical and safe method of obtaining a specimen of liver tissue satisfactory for microscopical study and causes very little discomfort to the patient.⁴⁻⁵ Liver biopsy is not generally recognized as a method for the diagnosis of miliary tuberculosis, and since references to its use in the literature are scanty,⁴⁻⁵ it is the purpose of this paper to offer the procedure as a practical method for diagnosing the disease.

The technic of punch liver biopsy using either the subcostal or the intercostal approach has been ably reported by Hoffbauer,⁶ Volwiler and Jones,⁵ Popper et al.,⁵ Topp and his co-workers¹⁰ and others.⁷ The Roth-Turkel¹¹ and the Silverman¹² biopsy needles are those in most common use and yield quite satisfactory specimens for histologic examina-

tion. This material can also be used for culturing.⁹ The mortality of the procedure is extremely low if the usual precautions are taken, Topp et al.¹⁰ having recently reported a series of 350 liver biopsies without serious complications or mortality.

The following case, recently observed at the University of Virginia Hospital, illustrates the diagnostic value of this procedure in substantiating a suspected diagnosis of miliary tuberculosis.

CASE REPORT

A 26-year-old Negro had been well until 5 weeks before admission, when he first had a severe pleuritic pain in the right side of the chest. This was associated with a hacking cough, chills, fever, drenching sweats, anorexia and weight loss. A few days later he was admitted to another hospital, where he went progressively downhill and became critically ill and semistuporous. The temperature varied between 101 and 104°F. An x-ray film of the chest was reported as suggestive of miliary tuberculosis but was considered more consistent with a fungous infection. Penicillin, sulfonamides, aureomycin and a few doses of streptomycin were tried without effect, and the patient was transferred to the University of Virginia Hospital on March 15, 1949 for further studies.

Physical examination revealed an emaciated patient who appeared acutely ill. The other significant findings were in the chest. There was splinting of the right side of the thorax, with slight to moderate dullness up to the fourth and fifth ribs anteriorly. A few bubbling rales could be heard in the right base, and in the region of the right apex there were a few crepitant rales.

The temperature was 102°F, the pulse 95, and the respirations 25. The blood pressure was 110/70.

scattered fibrosis, and many of the small arteries showed a hyaline intimal thickening encroaching upon the lumen.

The narrowing observed at the coronary ostia was due to a hyaline fibrous tissue containing an occasional lipoid-laden macrophage. There were many focal infiltrations with round cells. Some of these were found in the vessel walls near the junction of media and intima, the most marked infiltration was in the adventitia around the vasa vasorum. Sections taken through the site of obstruction in the innominate and subclavian vessels demonstrated a similar hyaline thickening of the intima, with focal infiltrations of round cells. The media of the innominate artery showed marked destruction and replacement with a vascular fibrous tissue (Fig 2 and 3),

FIGURE 3 Section of the Innominate Artery, Showing the Destructive Process in the Media under Higher Power (Elastic-Tissue Stain)

similar less marked changes were seen in the elastic tissue of the subclavian artery and the coronary arteries near their orifices.

Multiple sections through the aortic wall showed similar changes, focal infiltrations with round cells, especially around the vasa vasorum, marked intimal proliferation due to a hyaline fibrous tissue, and patchy irregular destruction of the elastic tissue of the media and replacement with a vascular fibrous tissue. There was intimal proliferation in the vasa vasorum. Small atheromatous pools were occasionally seen but contributed little to the over-all picture.

Levaditi's silver stains on all tissue blocks failed to reveal any recognizable spirochetes.

The final pathological diagnoses were as follows: syphilitic aortitis, with aneurysm of the terminal portion of the ascending aorta, syphilitic endarteritis involving the right and left coronary orifices and the orifices of the innominate artery and the left subclavian artery, subendocardial infarction of the left ventricle, cardiac failure as evidenced by passive congestion of the liver and abdominal viscera, and by bilateral hydrothorax, and anomalous origin of the left common carotid artery.

DISCUSSION

Stenosis of the coronary ostia with subsequent myocardial infarction is well described in the literature.^{1,5} Involvement of the coronary arteries in their course in the myocardium and involvement of other arteries of medium and smaller size is well known. The classic pathological picture is primarily an endarteritis of the vasa vasorum in the adventitia, with a secondary but nonsyphilitic intimal proliferation in response. There is also a marked destructive process involving the elastic tissue in the larger vessels, with replacement by fibrous elements.

In spite of the common pathological picture, there is difficulty in making the clinical diagnosis of ostial stenosis. Woodruff⁶ has cited this difficulty and has commented upon the rarity of myocardial infarction due to ostial stenosis in the absence of thrombosis. Associated thrombosis is usually on the basis of unrelated atheromatosis.

Obliteration of unilateral or bilateral radial pulsations is not uncommon in aneurysm of the arch, several recent reports have described the occurrence of a deficient pulsation in one or both upper extremities in association with syphilis and in the absence of a demonstrable aneurysm.^{7,8} In one of these cases,⁸ the pulse returned to normal after a course of arsenic therapy. No pathological material was presented.

Current observations⁹ indicate that adequate heavy-metal therapy usually results in the disappearance of the inflammatory process in aortitis. The place and efficacy of penicillin in the treatment of late cardiovascular syphilis is as yet undefined.^{10,11} Certainly 6,000,000 units of penicillin administered in the case reported above did not remove the evidences of active inflammatory processes although no recognizable spirochetes were to be found. It is perhaps confirmatory of the concepts of Moritz,¹ Saphir,² and Warthin⁸ that there was no regression of the secondary intimal proliferation, which was the actual obstructing agent in these vessels.

The electrocardiographic findings immediately prior to death were strongly suggestive of the total deficiency of the coronary supply as opposed to the solely focal changes more common in the usual atherosclerotic thrombosis. This case is being presented elsewhere as part of a series with electrocardiographic demonstration of subendocardial ischemia.¹²

In retrospect, then, it is possible to reach a diagnosis on the basis of the positive serologic test for syphilis, the unremitting angina and subsequent myocardial infarction, the aberrations of the pulses and the electrocardiograms suggesting "global ischemia." There is no satisfactory explanation of the patient's statement that he had always had deficient radial pulses. The pathological picture was clearly that of a syphilitic process and not that

MEDICAL PROGRESS

STUDIES ON THE RELATION OF PITUITARY-ADRENAL FUNCTION TO RHEUMATIC DISEASE*

GEORGE W THORN, M D,† THEODORE B BAYLES, M D,‡ BENEDICT F MASSELL, M D,§

 JOSEPH E WARREN, M D ††

DURING the past few years it has become increasingly evident that the adrenal cortical hormones exert a marked influence on a wide variety of metabolic processes in man. The over-all effects exerted by these hormones may be divided into three general groups: an electrolyte-regulating effect, the regulation of the rate of utilization of carbohydrate, protein and fat, and an androgenic and anabolic effect.

NATURE OF ADRENAL CORTICAL ACTIVITY

Electrolyte-Regulating Effect of Adrenal Cortical Steroids

This is characterized by urinary retention of sodium and chloride, increased excretion of potassium, increased plasma and extracellular fluid volume.¹ It has also been shown that desoxycorticosterone-like steroids decrease the concentration of sodium and chloride in sweat.² The most potent electrolyte-regulating adrenal steroid is 11-desoxycorticosterone, which has been synthesized. The 11,17-oxysteroids (Compounds E and F) exert a relatively weak sodium-retaining effect³ (Fig 1).

Unfortunately, there is no direct measurement of circulating "salt" hormone. Therefore, the activity of such steroids must be estimated indirectly, by changes in the renal excretion of sodium, chloride and potassium, by alteration in the mineral composition of thermal sweat and by changes in hematocrit and body weight.

Regulation of Intermediary Metabolism by 11-Oxysteroids and 11, 17-Oxysteroids

The second group of metabolic activities modified by the adrenal cortex involves the regulation of

carbohydrate, protein and fat utilization, control of lymphoid tissue and circulating eosinophils. The administration of this type of compound is characterized by the following effects:

An increase in blood glucose level and liver glycogen stores.

An increased conversion of protein to carbohydrate (increased gluconeogenesis). Recent studies indicate that this effect is accomplished, not by an increased catabolism of body protein, but rather by diverting amino acid radicals to pyruvic acid and glucose (antianabolic effect).

An increased mobilization of depot fat and its enhanced utilization, thus sparing carbohydrate. An increased intestinal absorption of fat.

FIGURE 1 Relation of Chemical Structure to Sodium-Retaining and Carbohydrate-Regulating Effect

has been observed after the administration of this group of steroids, and although relatively unimportant calorically, it is of theoretical interest.

An increase in the renal clearance of uric acid, resulting in the excretion of large quantities of urate, both in normal subjects and in patients with gout.

A lysis of fixed lymphoid tissue and a transitory decrease in circulating lymphocytes. A somewhat more permanent effect is observed on the circulating eosinophils, which almost completely disappear from the blood during the period of action of the hormone.

††Chief of medical department, House of the Good Samaritan.

Examination of the blood showed a red-cell count of 4,300,000, with a hemoglobin of 13 gm., and a white-cell count of 5000, with 74 per cent neutrophils. Repeated blood cultures were negative. No acid-fast bacilli were found on several examinations of the sputum, gastric washings and direct bone-marrow smears. Specimens from each of these were also cultured for tubercle bacilli. Tuberculin and histoplasmin skin tests were negative, as were studies of the urine, stool and spinal fluid. Bone-marrow examination showed nothing pathognomonic, but there was an increase in plasma cells of 5 to 10 per cent.

X-ray films of the chest showed both lung fields to be involved with a miliary type of nodulation. When the examination was repeated 2 days later areas of miliary density were again seen scattered throughout both lung fields but were thought to be more suggestive of a fungous disease than of typical miliary tuberculosis.

The temperature ranged between 101 and 105°F, and the patient continued to look critically ill. Dihydrostreptomycin was started on the 3rd hospital day, since it was believed that the patient probably had miliary tuberculosis.

A punch liver biopsy was done on the 4th hospital day by the intercostal route, and the histopathological report* was as follows:

Throughout this liver tissue are many small lesions that are rather typical small tubercles. The center of the lesions contains some necrotic material, around the margins of the lesions epithelioid cells, numerous lymphocytes and an occasional giant cell can be seen. Special staining techniques for acid-fast bacilli reveal the presence of a few acid bacilli in these tubercles.

The diagnosis was miliary tuberculosis of the liver.

After the biopsy report the dosage of streptomycin was increased to 3 gm. daily, and promizole was begun in a dosage of 1 gm. every 6 hours. On the 6th day of streptomycin therapy the temperature started gradually down. The appetite began to improve and soon became enormous, the patient often consuming six large meals a day. Three blood transfusions were given to correct an anemia that had developed. At the end of the 4th week of hospitalization the bone-marrow culture was reported positive for tubercle bacilli. The patient continued to improve and to gain weight and was discharged to a sanatorium.

DISCUSSION

As illustrated in this case, liver biopsy may offer a practical method for confirming a diagnosis of miliary tuberculosis when other methods fail. The diagnosis was strongly suspected in this patient but the chest x-ray films were equivocal and the usual measures for immediate bacteriologic substantiation were unsuccessful. Even though streptomycin had been started in this case, punch biopsy was able to establish the diagnosis.

It should be emphasized that preliminary cultures and sputum examinations should first be carried out

intensively. It is our opinion that if the diagnosis of miliary tuberculosis is strongly suspected but cannot be immediately confirmed, streptomycin therapy should be started and liver biopsy considered for early confirmation of the diagnosis. A conclusive diagnosis early in the course of the disease would be helpful since one could then concentrate all effort on the proper treatment of the tuberculosis without subjecting the patient to other diagnostic tests and therapeutic trials in an attempt to eliminate other diagnoses. The initiation of streptomycin therapy before or after performance of the liver biopsy should minimize the risk of further spreading of the disease. It seems, however, illogical to place much emphasis on the hazard of further complicating the disease in this way, since widespread hematogenous diffusion of the bacteria to practically all organs has already occurred.

With the correct diagnosis of miliary tuberculosis quickly and easily established by punch liver biopsy, treatment can be instituted with less delay, and a better prognosis can thus be made possible.

SUMMARY

Punch liver biopsy is offered as a relatively simple, safe and practical method for the diagnosis of miliary tuberculosis when other procedures fail. A case is presented to illustrate its value.

DURING the past few years it has become increasingly evident that the adrenal cortical hormones exert a marked influence on a wide variety of metabolic processes in man. The over-all effects exerted by these hormones may be divided into three general groups: an electrolyte-regulating effect, the regulation of the rate of utilization of carbohydrate, protein and fat, and an androgenic and anabolic effect.

NATURE OF ADRENAL CORTICAL ACTIVITY

Electrolyte-Regulating Effect of Adrenal Cortical Steroids

This is characterized by urinary retention of sodium and chloride, increased excretion of potassium, increased plasma and extracellular fluid volume.¹ It has also been shown that desoxycorticosterone-like steroids decrease the concentration of sodium and chloride in sweat.² The most potent electrolyte-regulating adrenal steroid is 11-desoxycorticosterone, which has been synthesized. The 11,17-oxysteroids (Compounds E and F) exert a relatively weak sodium-retaining effect³ (Fig 1).

Unfortunately, there is no direct measurement of circulating "salt" hormone. Therefore, the activity of such steroids must be estimated indirectly, by changes in the renal excretion of sodium, chloride and potassium, by alteration in the mineral composition of thermal sweat and by changes in hematocrit and body weight.

Regulation of Intermediary Metabolism by 11-Oxysteroids and 11,17-Oxysteroids

The second group of metabolic activities modified by the adrenal cortex involves the regulation of

carbohydrate, protein and fat utilization, control of lymphoid tissue and circulating eosinophils. The administration of this type of compound is characterized by the following effects:

An increase in blood glucose level and liver glycogen stores.

An increased conversion of protein to carbohydrate (increased gluconeogenesis). Recent studies indicate that this effect is accomplished, not by an increased catabolism of body protein, but rather by diverting amino acid radicals to pyruvic acid and glucose (antianabolic effect).

An increased mobilization of depot fat and its enhanced utilization, thus sparing carbohydrate. An increased intestinal absorption of fat.

FIGURE 1 Relation of Chemical Structure to Sodium-Retaining and Carbohydrate-Regulating Effect

has been observed after the administration of this group of steroids, and although relatively unimportant calorically, it is of theoretical interest.

An increase in the renal clearance of uric acid, resulting in the excretion of large quantities of urate, both in normal subjects and in patients with gout.

A lysis of fixed lymphoid tissue and a transitory decrease in circulating lymphocytes. A somewhat more permanent effect is observed on the circulating eosinophils, which almost completely disappear from the blood during the period of action of the hormone.

Examples of the "carbohydrate-regulating" adrenal cortical steroids or "S" hormone are the 11-oxysteroids, Kendall's Compounds A⁴ (11-dehydrocorticosterone) and B (Corticosterone) and the much more active 11,17-oxysteroids, Kendall's Compounds E⁵ (17-hydroxy-11-dehydrocorticosterone) and F (17-hydroxycorticosterone), demonstrated in Figure 1. The effects on lymphoid tissue and eosinophils are exerted only by the 11,17-oxysteroids. In all but electrolyte effects, the latter substances are superior to the 11-oxysteroids and to 11-desoxycorticosterone. Although the salt-retaining effect of the 11,17-oxysteroids is approximately one thirtieth that of 11-desoxycorticosterone, adequate salt retention may be obtained by the use of relatively large quantities of these substances. It is therefore possible, with Compounds E and F, to maintain a satisfactory electrolyte balance in Addison's disease if adequate quantities of either of these hormones are administered. It appears that Compounds E and F may compete with 11-desoxycorticosterone in its action on electrolyte regulation. Thus, in the presence of excessive sodium retention induced by desoxycorticosterone acetate, treatment with large doses of Compound E may result, not in further sodium retention, but in increased sodium excretion.

One may achieve an approximate measure of the amount of "carbohydrate-regulating" factors secreted by following the urinary excretion of 11-oxysteroids or "cortin-like" substances,⁶ more correctly called "neutral reducing steroids", more simply, by noting a fall in the level of the circulating eosinophils referable to a rise in the circulating 11, 17-oxysteroids, or by observing the rise in the urinary uric acid-creatinine ratio, which follows an increased blood level of 11-and 11,17-oxysteroids.³ Recent evidence suggests that the adrenal cortex contains predominantly Compound F.⁷

Androgenic and Anabolic Effect of Adrenal Androgens

The third group of adrenal steroids are those referred to as the adrenal androgens or "N" hormone. It is assumed that these substances exert an effect similar to that of the testicular androgens, which consists of masculinization, with retention of nitrogen, phosphorus, potassium, sodium and chloride.⁸ This effect has been characterized as the androgenic or anabolic hormone effect. In the female it is evident that nearly all androgenic effect is derived from the adrenal cortical androgens, whereas in the male, the adrenal androgens appear to account for only two thirds of the androgenic substances, the remainder being derived from the testes. Adrenal androgens are related in structure to testosterone, but carry an oxygen group in position 11 (adrenosterone).

The secretion of androgenic substances or the administration of such steroids is evidenced by a

relatively small rise in urinary 17-ketosteroids, their excretory product.

PRACTICAL CONSIDERATIONS IN ADRENAL HORMONE THERAPY

Two groups of adrenal cortical hormone preparations are available commercially at the present time* whole adrenal cortical extracts derived from beef or hog adrenal glands and synthetic desoxycorticosterone acetate.

In cases of adrenal insufficiency the salt-retaining factors are easily substituted for by the administration of synthetic desoxycorticosterone acetate (DCA) in the form of a solution in oil (5 mg per cubic centimeter), a macrosuspension in various solvents, or in the form of subcutaneously implanted tablets or pellets weighing 125 mg or 75 mg each. Such pellets give off 0.5 and 0.3 mg, respectively, of DCA daily. These substances are ineffective in the therapy of rheumatic diseases.

Substitution therapy with "carbohydrate-regulating" factors has in the past been possible by the administration of whole extracts of beef or hog adrenal glands. Such commercial extracts contain relatively small quantities of the known steroid hormones. Aqueous whole adrenal extracts are about one tenth as potent as Lipo-adrenal Cortex (Upjohn), a concentrate of hog adrenal gland in oil, each cubic centimeter of which is equivalent to 2 mg of Compound E. In the treatment of diseases such as rheumatoid arthritis, very large quantities of whole adrenal extract will obviously be required to induce an effect comparable to that obtained from 50 to 100 mg of Compound E daily. By 1950 Compound E acetate should be available as a crystalline suspension in saline solution. Compound F, which has not been synthesized, is derived from hog adrenal glands. Doses of the same order of magnitude as Compound E acetate will probably be required in the treatment of rheumatoid arthritis. However, because of the greater solubility of Compound F, it will be necessary to increase the frequency of administration, as compared with Compound E acetate.

PITUITARY ADRENOCORTICOTROPHIC HORMONE (ACTH)

Since purified pituitary adrenocorticotrophic hormone has become available in quantities adequate for clinical investigation, it has been possible to study the effect of administering this trophic substance on the secretion of adrenal steroids in man.^{9, 10}

*Whole adrenal cortical extracts derived from beef adrenal glands in aqueous solution for intramuscular or intravenous use assayed biologically in 10-cc and 50-cc vials (for example, Adrenal Cortex Extract, Upjohn Company; Adrenal Cortex Extract, Wilson Laboratories and Eschatin Parke Davis) and from hog adrenal glands in sesame oil for intramuscular use assayed against crystalline adrenal steroids in 5-cc vials (Lipo-adrenal Cortex, Upjohn Company). —Oral preparations of adrenal cortical extract are available but relatively ineffective in the doses employed. Desoxycorticosterone acetate (DCA) of synthetic source in oil for intramuscular use in 10-cc vials (Cortate, Schering Corporation; Doxa, Hoffmann-La Roche Incorporated and Percorten, Ciba Pharmaceutical Products Incorporated). Other DCA preparations include a water soluble glucoside pellets for subcutaneous implantation, macrocrystalline suspensions and sublingual tablets and solutions.

effectiveness as an adrenal cortical stimulator since endogenous ACTH production is inhibited by a rising titer of adrenal cortical steroids. This inherent disadvantage will be found with any substance that stimulates pituitary ACTH production.

STIMULATION OF THE HYPOTHALAMIC-PITUITARY-ADRENAL-CORTICAL SYSTEM BY STRESS

Anterior hypothalamic centers have recently been shown to form an essential link in the activation of pituitary ACTH secretion following conditions of stress, as well as epinephrine administration.¹⁶ Upon nervous stimulation or contact with circulating epinephrine, a humoral substance appears to be secreted by cells of the anterior hypothalamus, which stimulates ACTH secretion.

FIGURE 4 *Epinephrine and ACTH Tests in Rheumatoid Arthritis*

Through this neurohumoral system, the adrenal cortex may be activated to secrete 11,17-oxysteroids by a variety of nonspecific stresses and emotional factors (Fig 3).

Depression of circulating eosinophils has been demonstrated in a variety of moderate stresses, but the extent to which adrenal cortical activation may be accomplished by such nonspecific means awaits further investigation. It appears that the stimulatory effect upon the central nervous system of such noxious stimuli is the basis of pituitary ACTH activation. Whereas epinephrine is a good eosinolytic agent, nor-epinephrine is practically devoid of such action and is characterized pharmacologically by the near absence of any central-nervous-system stimulatory effect as compared to epinephrine.

Adrenal cortical reserve was measured by means of four-hour and forty-eight-hour ACTH tests, or both, in 22 patients with rheumatoid arthritis.¹⁷ The four-hour ACTH test using the intramuscular injection of 25 mg of ACTH and its effect on the circulating eosinophils four hours later was done on 10 patients, 8 of whom showed normal or low normal response (Fig 4). One patient who did not respond subsequently proved to be refractory to

therapy with ACTH as well. This essentially normal response in all but 1 of the group suggests that the available reserve of the adrenal cortex was not noticeably impaired by the rheumatic state. This concept was confirmed by the results of the forty-eight-hour tests, which in most cases were a continuation of the four-hour tests and were carried out using 10 mg of ACTH every six hours. All the known functions of the adrenal cortex were stimulated in all but 1 of the 10 patients.

The epinephrine test, which consists of the administration of 0.3 mg of epinephrine subcutaneously and determination of the fall in eosinophils at the end of four hours, was carried out on 14 patients with rheumatoid arthritis. The average fall of 50 per cent was slightly less than that in a similar group of normal subjects, who showed a mean 64 per cent fall (Fig 4). However, the spread of the results in the tests on patients with rheumatoid arthritis was considerably greater than that in the normal control group. Several of the patients who failed to respond normally to epinephrine re-

FIGURE 5 *Changes Following Forty-Eight Hours of ACTH Administration in Rheumatoid Arthritis*

sponded well to ACTH. Such a dissociation may be fortuitous or else suggests a possible deficiency in the hypothalamic-pituitary link in adrenal cortical activation (Fig 3).

EFFECT OF ACTH THERAPY ON RHEUMATOID ARTHRITIS

After the discovery by Hench, Kendall, Slocumb and Polley¹⁸ of the Mayo Clinic, that Compound E, given in large doses (100 mg per day), is effective in the treatment of rheumatoid arthritis, studies were made on the effect of the prolonged administration of ACTH to patients with rheumatoid arthritis. Ten patients were treated for from two to fourteen days with 40 mg of ACTH per day, given in divided doses of 10 mg every six hours. Of the patients treated, 5 were males and 5 females, varying in age from twenty-five to sixty-one years, the arthritis

was severe or moderately severe in 9 cases and mild in 1 case, and the duration of the disease varied from three months to twenty-eight years. In every case—that is, 9—in which the adrenal cortex responded improvement occurred. Two patients were treated for two weeks, and 8 for forty-eight hours. Within twelve to twenty-four hours of the initial administration of ACTH, clinical improvement was observed, in every way similar to that reported by the Mayo Clinic group who used 100 mg of synthetic Compound E daily.¹² The most characteristic immediate change was loss of stiffness in the joints. This was followed by improvement

in the joints, a rise in sedimentation rate and a loss of the euphoria.

Milder cases of rheumatoid arthritis show a somewhat more lasting effect after ACTH therapy, although the majority of cases return toward, but do not reach their status before treatment.

The reversion to pre-treatment status may be minimized by withdrawal of the adrenal cortical stimulation gradually. Thus, after 10 mg of ACTH intramuscularly every six hours, the same dose was given every eight hours for a week, then every twelve hours for another week, and then once a day for a short period before being discontinued altogether.

Because of the limited quantities of synthetic Compound E and natural ACTH that are available, attempts were made to increase the degree of pituitary adrenal stimulation by less specific methods. Since epinephrine has been shown to stimulate ACTH production in man, patients with rheumatoid arthritis were given a stimulating dose of epinephrine every six hours throughout the day and night. This therapy in 2 patients with rheumatoid arthritis resulted in a very slight but definite improvement, although, again, the maximum improvement observed was far less than that which occurred with ACTH or which might have been expected

FIGURE 6 Results of Treatment with ACTH

in the patient's general sense of well-being, culminating in a euphoric state. Since this is found in patients with Addison's disease on Compound E therapy it is not related solely to decreased pain on motion.⁵ With more prolonged administration, there was increased range of motion in the joints and loss of pain. Objective evidence of improvement was found in a progressive fall in the blood sedimentation rate, often reaching normal levels after about a week. Evidence for a generally increased adrenal hormone secretion in these patients given ACTH was provided by a sustained fall in the level of circulating eosinophils, by a marked rise in 17-ketosteroid excretion and by sodium retention. Illustrative cases are shown in Figure 5 in their reaction to forty-eight hours of ACTH (95 mg). It will be noted that the patient who failed to show any improvement on forty-eight hours of ACTH did not have an eosinophil fall, although urinary 17-ketosteroids rose. The patient who showed only 1+ improvement was the single one of the group whose arthritis was initially mild. A typical case on prolonged therapy with ACTH is presented in Figure 6.

Withdrawal of ACTH therapy after two to fourteen days of treatment in 10 patients was followed in twelve to twenty-four hours by a partial return of symptoms including stiffness and pain

FIGURE 7 Effect of Epinephrine Treatment on Subjects with Rheumatoid Arthritis

Note the ineffectiveness of a 0.2-mg dose of epinephrine

with 100 mg of synthetic Compound E. Definite adrenal cortical activation occurred although apparently not sufficient in terms of its beneficial effect on the rheumatoid arthritic state (Fig. 7). The use of epinephrine at the termination of a course of ACTH holds promise as a means of increasing endogenous ACTH production and of buffering the sudden falling off in adrenal cortical activity, which invariably follows the discontinuance of ACTH. A number of methods of nonspecifically stimulating the pituitary to increase its ACTH output, and thereby the adrenal cortical secretion, are now being studied in patients with rheumatoid arthritis.

In addition to the studies carried out with ACTH and epinephrine, an attempt was made to improve the clinical condition of patients with rheumatoid arthritis by the administration of large quantities of adrenal cortical extract. Two cc of Lipo-adrenal Cortex (Upjohn) were given intramuscularly, every three or four hours, for one to three days, to 5 patients with rheumatoid arthritis. The total daily dose of Lipo-adrenal cortex was 12 to 15 cc. This corresponds to approximately 120 to 150 cc of aqueous whole adrenal extract. Patients with rheu-

matoid arthritis given this treatment showed very slight improvement, but the magnitude of change was in no way comparable to that observed after ACTH in our group or Compound E as described by the Mayo Clinic group. This relative ineffectiveness appears, in all probability, to be due to the fact that the total amount of extract administered contained much less than the equivalent of 100 mg of Compound E, or the quantity of Compound E or F released by the adrenal cortex upon stimulation by 40 mg of ACTH, which was given in our studies.

illustrative case in an eleven-year-old girl is shown in Figure 8. This patient was given ACTH early in her second known rheumatic attack, which was associated with subcutaneous nodules, arthritis, pericarditis and myocarditis, as suggested by a protodiastolic gallop rhythm and electrocardiographic changes. The patient was taken off acetylsalicylic acid three days before treatment with ACTH was begun. It will be noted that all the known adrenal cortical secretions appeared to be increased by ACTH, although the relative proportion by which the individual factors were augmented cannot be ascertained by current analytical methods. The posterior pituitary-like effect of Armour ACTH and the consequent retention of water lead to a rapid weight gain in most subjects being given ACTH. In a patient with incipient heart failure such a possibility is very undesirable.

FIGURE 8 Clinical Course of a Girl with Acute Rheumatic Fever on ACTH Treatment. Sodium and potassium values refer to the daily urinary output in milliequivalents on an approximately constant diet.

FIGURE 9 Effect of ACTH on a Patient with Disseminated Lupus Erythematosus.

matoid arthritis given this treatment showed very slight improvement, but the magnitude of change was in no way comparable to that observed after ACTH in our group or Compound E as described by the Mayo Clinic group. This relative ineffectiveness appears, in all probability, to be due to the fact that the total amount of extract administered contained much less than the equivalent of 100 mg of Compound E, or the quantity of Compound E or F released by the adrenal cortex upon stimulation by 40 mg of ACTH, which was given in our studies.

EFFECT OF ACTH ADMINISTRATION ON RHEUMATIC FEVER

The response to ACTH in patients with acute rheumatic fever is more striking than that obtained in patients with rheumatoid arthritis, in whom previous joint deformities persist in spite of ACTH-induced improvement. To date, 3 cases of acute rheumatic fever have been treated for periods varying from eight to fourteen days, with 10 mg of ACTH given intramuscularly every six hours. An

However, in the limited number of cases treated and with the dose of ACTH employed, it was found that the improvement in cardiac efficiency, with its beneficial effect on renal circulation, led to an increased urinary volume, rather than to water retention during a period of a week. The over-all benefits were identical with those obtained with Compound E acetate.¹⁹

EFFECT OF ACTH ADMINISTRATION ON DISSEMINATED LUPUS ERYTHEMATOSUS

Three patients with acute disseminated lupus erythematosus showed marked clinical improvement, with rapid disappearance of the typical butterfly rash, when given 10 mg of ACTH intramuscularly every six hours. A representative case is shown in Figure 9. The low initial eosinophil count, also found in another case, is a consequence of bone-marrow hypoplasia with normal adrenal cortical function, rather than a sign of greatly increased adrenal cortical activity as in Cushing's syndrome, in which a marked eosinopenia is diagnostic.³ It should be noted that the gamma globulins, normally 12 to 14 per cent of the total protein, did not fall

below 20 per cent during the course of ACTH therapy, and yet the sedimentation rate was decreased and the patient was clinically improved.* It is also of interest that the initial, striking clinical improvement was obtained before any change in the circulating gamma globulins. Again, all major adrenal cortical functions appeared activated. Forty milligrams of ACTH was given daily for thirteen days, followed by 20 mg daily for four days. Five days after discontinuation of ACTH therapy, the characteristic leukopenia, elevated sedimentation rate and enlarged, tender spleen returned. In spite of this, the patient was still feeling well, and the rash had not reappeared. The treatment had thus led to striking temporary improvement, which left the patient in a better clinical state but did not lead to a cure. Two subsequent ACTH courses following partial regression in this patient showed beneficial effects lasting up to six weeks.

EFFECT OF ACTH ADMINISTRATION ON GOUTY ARTHRITIS

In a study of the effect of ACTH on patients with gouty arthritis, it was found that treatment with the hormone caused a large increase in urinary uric acid excretion, with a concomitant fall in serum uric acid levels. The clinical improvement was striking and rapid. This improvement was characterized by increased joint mobility, decreased pain and softening of tophi. Although the rise in uric acid excretion was no greater than that achieved

DISCUSSION

Rheumatic fever, disseminated lupus erythematosus and rheumatoid arthritis may be viewed as related mesenchymal diseases, characterized by a nonspecific inflammatory reaction, presumably brought on by a peculiar susceptibility of the host to certain bacterial or tissue products.²² Such pathologic states are apparently favorably altered by a sudden increase in the titer of circulating 11, 17-oxysteroids or related compounds of adrenal origin. With a sudden increase in the level of these steroids, the progress of the inflammatory reaction in heart, vessels and synovia is temporarily arrested. The majority of patients with these diseases seem to possess normal adrenal cortical reserve function, but appear incapable of increasing the activity of their adrenal cortex spontaneously. Is such an activation an essential part of the normal defense mechanism? If so, is it absent in those afflicted with mesenchymal disease? Or is the massive activation of adrenal cortical hormone production by ACTH merely a therapeutic implement acting favorably upon the patient's reaction pattern to the disease directly or by neutralizing some biologic antagonist? Evidence in support of this concept is the fact that 100 mg of Compound E is needed to alter significantly the course of rheumatic diseases, whereas patients with complete adrenal insufficiency may be maintained with 10 to 20 mg daily. Effective therapy is only attained when the level of hormone is increased, to supernormal levels.

Obviously, ACTH therapy will only be effective in patients in whom a normal adrenal cortical response is obtained. A marked decrease in circulating eosinophils following ACTH therapy is a valuable indication of increased secretion of 11, 17-oxysteroids, which appear specific in their ability to depress circulating eosinophils¹⁷ and lase lymphoid tissue and which, to date, are the only type of steroid that has been shown to exert a beneficial effect in rheumatic disease.¹⁸ Since they are synthesized from bile acids, the supply of these steroids will always be limited, therefore, a search for 17-oxysteroids derived from cholesterol or plant sterols and their trial in the rheumatic state is of great practical importance. ACTH, too, is limited by the number of pituitary glands available at any one time, thus, the search for effective nonspecific pituitary-adrenal stimulants must be continued.

The mode of action of 11, 17-oxysteroids in these diseases is unknown. Improvement is observed in most patients within four to six hours. The blood sedimentation rate usually falls within forty-eight hours after treatment is begun, but the maximal change may not occur for ten to fourteen days. The initial changes that occur, such as loss of stiffness and increased capacity to move joints without pain suggest a decrease in some "stiffness factor" and an immediate reduction in the chronic inflam-

FIGURE 10 Effect of ACTH on Severe Gout

by the administration of 5 gm of acetyl salicylic acid per day,²⁰ the over-all clinical improvement was much more marked with ACTH administration. Upon withdrawal of ACTH, a mild gouty attack occurred after two days. This phenomenon has been reported by Hellman.²¹ An illustrative case is shown in Figure 10.

*The electrophoretic analyses were carried out by Dr. W. F. Leve and Dr. J. McLean of Harvard Medical School.

matory reaction. A possible cause of these changes is the effect of the hormone on tissue permeability.²³ The singular specificity of adrenal steroids in their action on rheumatic diseases is suggested by the prompt response to Compound E and the ineffectiveness of desoxycorticosterone and dehydrocorticosterone acetate. Excessive DCA treatment in patients with Addison's disease is often associated with increased stiffness of the joints or arthralgia, or both.²⁴ It is of interest that Selye²⁵ has been able to accumulate a large amount of experimental evidence suggesting that arthritis is induced in rats by the administration of excessive amounts of desoxycorticosterone, a finding recently confirmed in man.²⁶

The improvement in gout brought on by ACTH is apparently not due to increased renal uric acid clearance alone, but must also involve some direct effect on the joint tissue. Even though the effect of salicylates on the uric acid excretion is greater, the clinical improvement noted is far less than that with ACTH.

The dangers of continued ACTH or Compound E acetate treatment are principally the undesirable side-effects associated with a long-continued, high level of adrenal steroids. With chronic ACTH administration, one must be concerned with the possibility of persistent adrenal hyperplasia. Cushing's syndrome has been reported during the prolonged administration of Compound E.¹⁷ On 40 mg of ACTH per day this danger is minimal, and yet adequate adrenal cortical activation is achieved. With higher doses Cushing's syndrome is occasionally produced by ACTH as well. In all cases studied thus far on ACTH therapy there has been a rapid return of adrenal function to normal or subnormal levels. The pituitary ACTH mechanism is suppressed by exogenous ACTH and the adrenal cortex is stimulated, whereas with Compound E both the adrenal cortex and the anterior pituitary gland may become atrophic. Thus, withdrawal of Compound E therapy leads to a more acute, temporary adrenal cortical deficiency than the withdrawal of ACTH therapy. To minimize this sudden reduction in adrenal cortical activity, it appears desirable to administer ACTH for twenty-four to forty-eight hours after the withdrawal of Compound E therapy.

The beneficial effect of 11,17-oxysteroid therapy in the rheumatic diseases marks a great advance in therapy. Adrenal cortical hormone therapy does not, however, appear to affect the fundamental cause of the inflammatory changes that characterize these diseases. The use of adrenal cortical steroids or adrenal cortical stimulants will do much to further fundamental research in the field of rheumatic diseases. Their exact value as therapeutic agents remains to be worked out by long-continued therapy.

SUMMARY

The major metabolic changes induced in man by adrenal cortical steroids are described. The remarkable observations of Hench, Kendall, Slocumb and Polley on the effect of Compound E therapy in patients with rheumatoid arthritis have been extended by the use of pituitary adrenocorticotrophic hormone (ACTH). The status of the adrenal cortical function was ascertained and found to be essentially normal in 16 of 21 patients with rheumatoid arthritis. There appears to be a wide variation in the state of adrenal cortical function from patient to patient, without apparent correlation with the severity or manifestations of the disease. In 9 patients with rheumatoid arthritis in whom pituitary adrenocorticotrophic hormone was capable of stimulating the adrenal cortex to increased activity, there was striking clinical improvement and a reversal of abnormal laboratory findings. Three patients with rheumatic fever and 3 with disseminated lupus erythematosus were similarly improved by ACTH therapy, as was 1 case of gout.

With the present inadequate supply of synthetic Compound E acetate and pituitary ACTH, non-specific methods for stimulating an intact pituitary-adrenal system and naturally occurring adrenal cortical extract have been tried with little success in the treatment of rheumatic diseases.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

Weekly Clinicopathological Exercises

FOUNDED BY RICHARD C CABOT

TRACY B MALLORY, M D, *Editor*

BENJAMIN CASTLEMAN, M D, *Associate Editor*

EDITH E PARRIS, *Assistant Editor*

CASE 35401

PRESENTATION OF CASE

A five-year-old boy was admitted to the hospital because of a chronic cough.

He had been seen in the Children's Clinic one year prior to admission, when his mother stated that several months before, the patient had a severe cold, which seemed to hang on longer than normal. This cleared after several weeks but was followed by a persistent cough productive of a small amount of sputum of unknown character. Otherwise the patient was active and well.

The past history was noncontributory. A sister, ten years old, had had tuberculosis at the age of two and a half years, apparently as a result of contact with a grandmother, who died of this disease two years before the patient was brought to the clinic. It was stated, however, that the patient himself had never been brought in contact with the grandmother.

Physical examination at the time of the clinic visit showed a well developed and well nourished boy. The chest was clear to percussion, but wheezes, groans and coarse breath sounds were heard over the right side posteriorly. The rest of the physical examination was negative.

A roentgenogram of the chest showed collapse of the lateral portion of the right middle lobe, with emphysema of the medial portion (Fig 1). There was no evidence of mediastinal adenopathy.

Six weeks later the patient returned for bronchoscopy. The middle-lobe orifice was completely occluded by what looked like soft inflammatory tissue. There was reddening of the bronchus in this area. A biopsy taken at this time was sub-

FIGURE 1

sequently reported as showing chronic inflammation. Subsequent appointments were not kept, and the patient was not seen again until his present admission.

At this time the chest was clear and the general physical examination was negative except for a few small, shotty lymph nodes in the axillary and inguinal regions bilaterally.

Examination of the urine was negative. The hemoglobin was 12.4 gm and the white-cell count 11,000, with 47 per cent neutrophils, 46 per cent lymphocytes, 2 per cent monocytes, 4 per cent eosinophils and 1 per cent basophils.

A second roentgenogram of the chest showed continued evidence of involvement of the right

middle lobe, although the degree of atelectasis appeared less marked than on the previous examination one year before

On the fifth hospital day an operation was performed

DIFFERENTIAL DIAGNOSIS

DR WILLIAM BERENBERG We have here the story of a five-year-old boy whose disease started when he was three and a half years old. During all this time his general health remained excellent despite a severe, persistent cough. At the time of his first examination all the physical signs were suggestive of some obstructive phenomenon in the bronchus, and this impression was corroborated by radiologic examination as well as bronchoscopy. May we see the chest films now?

DR STANLEY M. WYMAN These films, which were taken over a three-month period, show very sharply defined, apparently segmental atelectasis in the right middle lobe, best demonstrated in the lateral view. The bronchi, as seen in these films, do not appear remarkable.

The second set of films, three months later, demonstrates definite clearing of the process. Films taken twelve days subsequently again show accentuation of the atelectasis and consolidation. This left anterior oblique film taken at the time of the original examination shows the right main bronchus, but unfortunately one cannot follow it down to the lower-lobe branches well.

DR BERENBERG Do you see any evidence of adenopathy?

DR WYMAN No.

DR BERENBERG At least there is no massive enlargement.

DR WYMAN There may well be small nodes, but I am not much impressed by them. I think that is a dubious question to settle in many cases.

DR BERENBERG These films do not add much to what we have already been told. We are thus faced with the question of determining the cause of this bronchial obstruction.

The likelihood of intrabronchial or pulmonary tumor is remote at this age. This benign course, negative biopsy, age and chest film make me believe that we need mention tumor only to exclude it.

The possibility of some congenital anomaly must be considered. The commonest malformations in this region are congenital stenosis and absence of cartilaginous rings. However, we lack the evidence of narrowing of the lumen necessary to consider this possibility seriously. Most patients with an anomaly of this type would not have remained asymptomatic for three and a half years. It would be difficult to explain the mass of soft inflammatory tissue occluding the middle-lobe orifice on this basis.

As one listens to the story, this case appears on the face of it to be a typical example of progressive

bronchiectasis in a five-year-old boy following a respiratory infection that resulted in persistent pulmonic collapse. He may very well have had unrecognized pneumonia with persistent atelectasis and progressive bronchiectasis in the involved segments. The history and physical findings are both in keeping with this diagnosis. The type and duration of cough are typical. The observation that this child was well developed and well nourished is not surprising, since we see very few children at this age with bronchiectasis who are not well above the tenth percentile for weight. Most of these children look and act well.

We are told that the middle-lobe orifice, on bronchoscopy, was completely occluded by soft inflammatory tissue. I have not seen this occur in children with post-pneumonic bronchiectasis. We have seen plugging of course, but the plugging in bronchiectasis results from the accumulation of secretions, from inspissation or occasionally from a blood coagulum, which may fill or occlude a bronchial lumen. It therefore seems to me necessary to postulate another mechanism in addition to the bronchiectasis to explain the material found at bronchoscopy. There is no mention of a specific change in the microscopical section of the biopsied material. We must assume that it probably did not exist and that what is grossly described was just inflammatory tissue. It is my opinion that this patient had bronchiectasis, although it was probably secondary to the primary cause of the bronchial occlusion.

DR BENJAMIN CASTLEMAN The report of that bronchoscopy was as follows:

Biopsy attempted. Very little if any tissue obtained.
Secretions aspirated. Some inflammatory tissue loosened,
coughed up and saved for biopsy tissue.

DR BERENBERG I think even that is unusual for ordinary post-atelectatic bronchiectasis. One may see a good deal of mucosal reddening and some inspissated material but hardly that degree of true inflammatory reaction, especially without visible hilar adenopathy on x-ray study.

In a group of cases of the so-called "middle-lobe syndrome" recently reported following pneumonia of the right lower lobe there has occurred drainage into the perihilar region sufficient to produce significant adenopathy. This may result in obstruction of the middle-lobe bronchus with or without ulceration into the bronchial lumen. This syndrome could explain the picture here, but since there are only about 20 cases reported in children, I should hesitate to make this diagnosis without a well established sequence of events.

If this patient had tuberculosis, as we are invited to believe by the family history, he probably had intrabronchial disease. Certainly, one cannot even start to discuss the question of tuberculosis without asking a number of questions. Was a tuberculin

test done? Was the aspirated material smeared for acid-fast organisms? Was this material cultured for tuberculosis? If so, what were the results?

DR CASTLEMAN Nothing is left out, intentionally, but I do not believe there was a smear

DR ALLAN M BUTLER The tuberculin test in a dilution of 1:1000 showed swelling but no redness

DR BERENBERG It seems extraordinary for swelling to occur without redness, one more often sees redness without swelling

DR BUTLER It seems extraordinary, if it was questionable, that that point was not investigated further

DR BERENBERG We have in the history the fact that this patient's sister and grandmother had tuberculosis. We have no information concerning the possible recent infectiousness of the sister. The statement that the patient had never been brought in contact with the grandmother may be misleading. Very often we obtain such a statement only to find that the patient was repeatedly shown to an infected grandparent and allowed in the same room although perhaps never held by her.

The state of well-being of this child is in keeping with intrabronchial tuberculosis at this age. Most children look the picture of health even with pulmonary lesions. Cough is not a common symptom in children with pulmonary tuberculosis as a matter of fact, but is a common symptom, of course, in intrabronchial lesions of any sort, including tuberculosis. Was fluoroscopy performed?

DR WYMAN No

DR BERENBERG It might be interesting to know if the emphysematous area changed during respiration, in order to try to decide whether the emphysema was compensatory or otherwise. This might be helpful in deciding about tuberculosis. The nature and course of this lesion are in keeping with what one would anticipate with juvenile tuberculosis. The absence of visible hilar lymph nodes and a defined pulmonary lesion are not at variance with this possibility. The presence of a few small, shotty inguinal and axillary lymph nodes is not unusual in any five-year-old child.

The interpretation of the aspiration biopsy is rather difficult. The amount of material one gets from the bronchial aspiration of the tiny lumen of a five-year-old child is limited, regardless of the lesion. If there was any nonspecific inflammatory reaction about a localized process, one would be more apt to aspirate that than the defined lesion. Most children with a tuberculous lesion of this type should be either considerably better or considerably worse in a year's time. It is not a static process and would ordinarily have cleared up or produced a bronchiogenic spread over this period. If smears had been done it would have been most helpful because the incidence of positive smears from material obtained on bronchoscopy in intrabronchial tuberculosis is higher than that from material ob-

tained in almost any other form of juvenile tuberculosis. Certainly one cannot exclude the diagnosis of tuberculosis on the information at hand, especially in the absence of a conclusively negative tuberculin test.

In any child with persistent cough, wheezing, atelectasis and evidence of bronchial obstruction, foreign body must be ruled out. In favor of foreign body is the patient's age. The commonest age is between three and five years. The fact that he had an upper respiratory infection at the onset does not bother me. In one way it is almost in keeping with this diagnosis because the incidence of aspiration is highest at the time of a common cold. I suppose that is because the child tends to have nasal obstruction and hence becomes a mouth breather. The deep inspiration following cough is conducive to the aspiration of any foreign body that the child happens to have in his mouth at that time. The clinical picture is in keeping with foreign body, and a negative bronchoscopy does not exclude the possibility of a tiny body imbedded in the wall or one lodged distal to the bronchoscopist's view. The thing that disturbs me is the fact that this disease was in the right middle lobe, which is an unusual site for a foreign body, the incidence in this lobe is only 6 to 8 per cent of all foreign bodies. The absence of a dramatic episode of coughing and choking is not unusual, especially since it might well go unnoticed in a child who then had a cold and cough. Nothing is mentioned of possible dental caries or preceding tonsillectomy. These are only two of many possible sources of aspiration to be considered. Putrefaction, if present, would favor the likelihood of aspiration, but its absence does not exclude it since any number of foreign bodies do not cause putrefaction.

I would favor the diagnosis of bronchiectasis secondary to the aspiration of a foreign body but am unable to exclude the possibility of tuberculosis without more evidence than that at hand. In addition this child had pulmonary atelectasis.

DR BUTLER Does Dr Sweet want to say a word?

DR RICHARD H SWEET When the patient was first seen on the Pediatric Service, the question of foreign body was considered and eliminated on the basis of bronchoscopic examination. I saw the boy at a later stage and to me it was a classic picture of involvement of the middle-lobe bronchus secondary to peribronchial lymphadenitis. We have seen a large number of cases like that. We have not always proved them to be due to tuberculosis. We all have seen the other group of which Dr Berenberg spoke, and I was surprised to hear it said that the number of reported cases was so small. We have an appreciable number here at the hospital but no one thought to report them as a group. It is interesting in this patient that one bronchial segment was collapsed and the other

emphysematous That was obvious at operation

The peribronchial lymph nodes were not enlarged but were very much involved in a marked peribronchial infiltration The artery and vein of the middle lobe were obscured by an infiltrative type of tissue, making dissection difficult and rather perilous, although we were able to isolate the vessels after much painstaking dissection, tying them independently In doing that, I discovered that one of the lymph nodes was calcified, and I then re-

FIGURE 2

marked that it was probably on a tuberculous basis The patient made a good recovery and has gone home

DR CASTLEMAN Do you see any specks that might be calcified lymph nodes?

DR WYMAN No, not even knowing the story

DR BUTLER Would you have operated if he had had positive smears for tuberculosis?

DR SWEET I would not hesitate to do so because I think he is far better off with the middle lobe out

CLINICAL DIAGNOSIS

Bronchiectasis, right middle lobe

DR BERENBERG'S DIAGNOSIS

Bronchiectasis, due to foreign body

ANATOMICAL DIAGNOSES

*Bronchial stenosis (middle lobe, lateral division)
produced by calcified tuberculous lymph nodes*
Pulmonary atelectasis, middle lobe, lateral segment

Miliary tubercles of lung

PATHOLOGICAL DISCUSSION

DR CASTLEMAN This is the entire middle lobe (Fig 2) From this specimen, one can see that one segment, which corresponds to the atelectatic portion on the x-ray film, is completely collapsed, whereas the other segment appears normal The cause of the obstruction in the collapsed segment is a small tuberculous calcified lymph node pushing against the bronchus but not eroding into the lumen In the lateral portion of the segment is a large caseous and calcified area of tuberculosis, which is, I believe, the primary focus An interesting and unexpected finding was the presence of small miliary tubercles, in both the collapsed and the aerated segments of the lobe, so that there must have been a hematogenous spread Some of these tubercles seem to be active, but others are fairly old We were unable to find any actual tuberculosis within the bronchus At the point of obstruction the mucosa seemed to be intact

DR SWEET It is purely a matter of pressure upon the bronchus from the exterior

DR CASTLEMAN Yes

CASE 35402

PRESENTATION OF CASE

A sixty-six-year-old Italian-born man entered the hospital for the first time complaining of cough and chest pain

He had enjoyed good health until four or five months before, when he experienced the onset of a hacking cough This was persistent and soon became productive of white, mucoid sputum Two months before admission he began to suffer pain over the left anterior thorax This was at first present only on severe coughing but rapidly became more severe until he was aware of pain at all times but particularly on deep breathing or with the slightest cough The pain was nonradiating in character and was unaltered by external pressure to the chest wall With the onset of chest pain he experienced increasing anorexia and weakness As his symptoms progressed his cough became more productive until he was bringing up half a cupful of white sputum daily A few weeks prior to admission he noted a change in pitch and timbre of his voice There was a weight loss of 25 pounds since the onset of the illness Hemoptysis, dyspnea, chills, fever and night sweats were specifically denied A review of the systems was otherwise

negative. No history of exposure to tuberculosis or to the various pathogenic dusts could be obtained. The patient had smoked two or three packages of cigarettes daily for thirty years but had voluntarily discontinued tobacco one month before admission.

Physical examination revealed a chronically ill man with signs of recent weight loss. There was no cyanosis or lymphadenopathy. The left pupil was larger than the right, but neurologic and ophthalmologic consultants denied the presence of a Horner syndrome. The trachea was not deviated. Dullness to percussion and diminished breath sounds were elicited over the anterior and posterior aspects of the left upper thorax. Fine rales were heard over both lung bases posteriorly. The heart was not enlarged, and there were no murmurs. There was a fullness in the right upper quadrant of the abdomen palpable three fingerbreadths below the costal margin. The spleen was not felt, and there was no abdominal tenderness. The prostate was three times the normal size, firm, regular and free of nodules. The fingers of the left hand had been amputated traumatically several years before. There was well developed clubbing of the remaining digits, with mild cyanosis. No peripheral edema was noted. There was weakness of the right lower facial nerve, but neurologic examination was otherwise negative.

The temperature was 99.2°F, the pulse 80, and the respirations 20. The blood pressure was 120 systolic, 70 diastolic.

The hemoglobin ranged from 13.0 to 11.4 gm, and the white-cell count from 41,000 to 57,500, with an average differential of 93 per cent neutrophils, 3 per cent lymphocytes, 3 per cent monocytes and 1 per cent eosinophils. Many band-form neutrophils were seen but the morphology was not altered otherwise. A sternal-marrow aspiration contained 85 per cent myeloid cells, 12 per cent erythroid elements and 4 per cent plasma cells. The myeloid-erythroid ratio was 8:1. A shift to the left in the myeloid series was described. Urinalysis showed a specific gravity of 1.022, a ++ test for albumin and no Bence-Jones protein, and there were 2 or 3 red cells and 3 to 5 white cells per high-power field and occasional casts in the sediment. The stools were guaiac negative. The spinal-fluid protein was 54 mg per 100 cc. The cell count was negative. The serum protein was 6.83 gm per 100 cc, with an albumin of 3.19 and 2.85 gm and a globulin of 3.98 and 3.64 gm per 100 cc. The nonprotein nitrogen was 28 mg per 100 cc. The alkaline phosphatase was 12.1 units per 100 cc. The calcium was 9 mg per 100 cc. The prothrombin time was 70 per cent of normal. The sputum cultures grew out colon bacilli and *Haemophilus influenzae*. Three cytologic examinations of the sputum were negative.

The chest x-ray films showed a flame-like area of increased density extending from the left lung root, which occupied the central half of the left

chest and obscured the left border of the heart. A bone series showed no evidence of metastatic lesions, but there were moderate degenerative hypertrophic changes of the spine.

Throughout his hospital stay the patient exhibited a slowly rising temperature reaching 102°F by the eighteenth day, after which it varied between 104 and 105°F. The pulse varied between 80 and 120. Respirations were consistently elevated between 25 and 40. Large doses of penicillin and streptomycin failed to alter the febrile course. A spinal puncture revealed clear spinal fluid under normal pressure. Jugular compression on the right side failed to elevate the pressure. Bronchoscopy showed narrowing of the terminal portion of the left-lower-lobe bronchus, with incomplete fixation. No intrinsic masses were seen, and the remaining bronchi appeared unaltered.

On the eleventh hospital day it was noted that the patient's voice had become increasingly hoarse, and that his speech was thick. Slowly progressive mental deterioration occurred, and he declined rapidly following a distinctly septic course, which terminated in death on the twentieth hospital day.

DIFFERENTIAL DIAGNOSIS

DR JOHN R. GRAHAM: I should like to review this patient's history at the end of his first day in the hospital. So far, we have a five-month story in a sixty-six-year-old man, the essential points of which are chronic cough, chest pain, increasing amounts of sputum, weight loss, weakness, nausea and the development of a change in his voice. That story, in itself, certainly makes one think very strongly of carcinoma of the lung. The physical examination, which was done on entry to the hospital, was perfectly consistent with such a diagnosis. The chest findings, the mass in the right upper quadrant, and the suggestion of some cerebral lesion are all perfectly consistent with that diagnosis also.

Before going on with the rest of the story, I wonder if we may look at the x-ray pictures made on the second day.

DR STANLEY M. WYMAN: The chest examination is a film taken with a portable apparatus showing an irregular area of density in the left midlung field. It seems to radiate out peripherally, and there is a suggestion of some mottled density in the right lung. The next examination, eleven days later, is more satisfactory and better demonstrates the central area of density, which in the lateral view appears to be located anteriorly, probably in the left upper lobe. Again, one sees indefinite areas of mottled density in the right lung throughout its entire distribution. There are old fractures of several right ribs, and probably several fractures on the left as well. It is impossible to trace the bronchial tree well on these films because of respiratory motion. The last films, which were taken in a search for metastases, show no definite bone destruc-

tion but they do show rather extensive degenerative changes in keeping with the patient's age and probable occupation

DR GRAHAM There were no subsequent films of the chest?

DR WYMAN These are all, apparently, no subsequent films were taken

DR GRAHAM I paused at that point because it seemed to me so far that this history was a fairly characteristic one, and that it is only as we go on that the diagnosis becomes involved. What had seemed to me a rather straightforward story is now complicated by some atypical findings and happenings. In the first place, the blood picture is unusual—the high white-cell count with the high percentage of neutrophils is certainly an unusual finding, and one's first thought is whether there was some fundamental blood dyscrasia, intrinsically connected with the lesion in the chest. One might wonder if the patient had a form of leukemia, with a chest complication. However, I think that the blood picture and the marrow findings were really not strikingly abnormal, showing a bit of a shift to the left in the white-cell series rather than a marrow full of very young leukemic cells. It does not really fit in with the diagnosis of leukemia—certainly not leukemia in the stage in which the patient appeared. He did not have a large spleen, an important lack that militates against that diagnosis. He had no significant anemia, so often present in leukemia. I am assuming rightly or wrongly that his voice changes were intrinsically connected with the mass in the chest and were based on involvement of the recurrent laryngeal nerve. We are not told what the vocal cords showed. I think the laryngeal involvement is unusual in the course of leukemia, even if the disease involves the lung. I am therefore betting against leukemia. I am more inclined to think that the high white-cell count and the increase in neutrophils were probably an accentuated response to infection.

There is one other thing that crosses my mind. In the days when we were using more sulfonamides, we used to see an occasional patient with a very high white-cell count. I remember one here with a count of 72,000, and others up to 100,000 have been reported as a response to sulfonamides. I wonder if by any chance this man had been given such a drug before entry to the hospital.

Other things that bothered me were the increasing fever and the general septic course. They did not respond to the ordinary, apparently adequate chemotherapy. This raises the question of whether he had a disease that was nonbacterial in origin—either virus or fungus. I also wonder whether he had disease involving some center in the brain that has to do with temperature regulation. In connection with this one immediately begins to think of the possibility of a Hodgkin lesion, which we

know will cause fever and occurs as an isolated finding involving the chest occasionally. I have not seen this type of blood-picture response to Hodgkin's disease, although one has to admit that the presence of eosinophils with this high white-cell count is rather an unusual finding in a leukocytosis due to infection, consequently, Hodgkin's disease with its accompanying eosinophilia has to be considered. Against the possibility of Hodgkin's disease is the rather progressive course of the illness in the absence of an enlarged spleen, and the lack of any obvious lymphadenopathy elsewhere.

One, of course, has to think of all the other lung diseases, tuberculosis, empyema, abscess, and bronchiectasis, which do not particularly look like this in my estimation, and even some of the fungous diseases or histoplasmosis, which could possibly produce this type of picture. I see no evidence in their favor.

I am brought back to the original diagnosis of carcinoma of the lung probably arising from a small bronchus or the alveolar cells, with involvement of the recurrent laryngeal nerve from regional lymph nodes, and very likely some involvement of the brain and liver and possibly even the kidneys. Simpson* reported a collection of cases of carcinoma of the lung some years ago in which the most common metastases were to the bones, regional lymph nodes, liver, brain, kidneys and adrenal gland, various other organs being affected also, but these were the most important and in about that order. In favor of difficulty with the liver we have some laboratory findings, that are significant—the inverted albumin-globulin ratio, the high alkaline phosphatase and the slightly disordered prothrombin time. It is hard to guess about the kidneys, since there was only one urine report, which showed albumin and a few red cells. This may have been a result of metastases to the kidney or a response to what I think must have been the cause of his fever—namely, secondary infection with some organism not sensitive to the antibiotics used.

I will end up with a diagnosis of carcinoma of the lung with metastases in the liver and probably elsewhere, in addition to secondary infection, most likely arising in the area of the tumor and terminal septicemia.

We are told that he had an enlarged prostate. From the description it apparently was not a malignant lesion but simply prostatic hypertrophy.

A PHYSICIAN Was the serology reported?

DR BENJAMIN CASTLEMAN I am sure it was taken, but the report was not put in the record.

DR JAMES H. TOWNSEND I wonder if he had a large carcinomatous abscess behind an obstructed bronchus that was responsible for this high leukocytosis?

DR CASTLEMAN A straight abscess?

*Simpson, S. L. Primary carcinoma of lung. *Quart J Med* 22:413-432, 1929.

DR TOWNSEND Yes, abscess arising from the tumor

DR ANDRIES QUERIDO I should like to comment about the leukocytosis. Such an extremely high leukocytosis is usually infectious in origin, either streptococcal or staphylococcal, but in such cases eosinophils are absent. The only other condition that I know of in which it is found and in which eosinophils are present is a highly necrotizing tumor, not an abscess. The white-cell count may go as high as 50,000 or 60,000. First of all, this illustrates that it is very worth while to count the eosinophils per cubic millimeter. It is a very easy thing to do. If this patient had 500 eosinophils per cubic millimeter, I would say not abscess, but a highly necrotizing carcinoma.

A PHYSICIAN Is it not true that carcinomas, particularly those of the kidney and liver, give rise to a high white-cell count without infection?

DR CASTLEMAN Yes, increased white-cell counts occur in renal-cell carcinoma, carcinoma of the lung and primary hepatoma.

DR QUERIDO An eosinophilia in hepatoma.

DR CASTLEMAN In hepatoma it is possible to find thrombi in the hepatic veins, and even in the portal radicles, which might account for some necrosis.

CLINICAL DIAGNOSES

Carcinoma of lung
Pseudoleukemia

DR GRAHAM'S DIAGNOSES

Carcinoma of lung with metastases in liver, probably elsewhere
Secondary infection
Terminal septicemia

ANATOMICAL DIAGNOSES

Carcinoma of lung undifferentiated, upper lobe with extensive necrosis and with metastases to lungs, bronchial lymph nodes, liver, adrenal glands and brain.

Atelectasis, compression type posterior apical and superior lingular segments upper lobe of left lung

Bronchiectasis, chronic severe

Pulmonary osteoarthropathy severe

Mieloid hyperplasia of bone marrow

Atherosclerosis, coronary artery and aorta, moderate

PATHOLOGICAL DISCUSSION

DR CASTLEMAN This patient's tumor was, as seen on x-ray study and as Dr Graham predicted, in the left upper lobe and was a solid mass that extended anteriorly and, in fact, went over the midline a bit. The tumor was extremely necrotic, not a true abscess, but merely necrosis of tumor. There was only one metastatic nodule close to the tumor and several metastatic nodules throughout the other lung. The anterior and mediastinal extension of the tumor was really extension rather than metastases to regional lymph nodes. There were numerous metastases to the liver, which accounted for the high alkaline phosphatase and other impaired liver-function studies. There were metastases to both adrenal glands, but none to the kidneys. The tumor was an undifferentiated one, in places it looked almost sarcomatous, with spindle-shaped cells. Mitoses were very common, and many cells had four or five nuclei such as one sees in undifferentiated sarcoma. On the other hand, when one studied the metastases where the tumor was not as undifferentiated, the cells were unquestionably of epithelial origin so that one would call it an undifferentiated carcinoma rather than an oat-cell, adenocarcinoma or squamous-cell lesion, which are the more usual types seen.

DR GRAHAM How about the brain?

DR CASTLEMAN It measured 5 mm in diameter in the left superior frontal gyrus.

DR QUERIDO Was the kidney stained for amyloid?

DR CASTLEMAN No, but there was nothing to suggest amyloid in the routinely stained sections.

DR GRAHAM I think that the fever was explained by the process that Dr Querido has suggested. That is interesting. More attention ought to be paid, perhaps to the eosinophil count.

REPORT OF THE HOOVER COMMISSION REVIEWED

THE duties of the Commission on Organization of the Executive Branch of the Government, known as the Hoover Commission, were "to investigate activities of the Executive Branch with the objectives of limiting expenditures as far as possible consistent with proper performance of essential services, doing away with overlapping and duplication, consolidating similar services and abolishing unnecessary ones, and defining the limits of executive function"

An analysis of the report of the Committee on Medical Services of the Commission was presented at the annual meeting of the Massachusetts Medical Society by Professor Hugh R. Leavell of the Harvard School of Public Health and appears as the leading article in this issue of the *Journal*

When the report was first released it became immediately apparent that the federal Government was spending far too much money on medical and public-health operations, most of the expenditures being made by the Veterans Administration, the armed forces and the Federal Security Agency. The taxpayer may well be aghast at the medical bill of \$1,250,000,000, incurred in 1948, even accustomed as he has become to governmental extravagance.

The chief present weaknesses in the health services are in the medical-care program rather than in public health and research. This consists of competition between agencies for scarce personnel, wasteful construction of hospitals without over-all planning, and failure to utilize existing facilities to the best advantage. A lack of centralized responsibility for the over-all federal health plan has resulted in the competition among agencies for scarce medical and technical personnel and in hospital construction regardless of the plans or needs of other agencies or of state and local facilities. Construction costs range from \$20,000 to \$51,000 per bed, with voluntary hospital construction estimated at about \$16,000 per bed. The dollar has apparently two values — fifty cents to the average citizen, and a quarter when spent by the Government! The geographic location of Veterans Administration Hospitals has also been unwise, and the policy regarding beneficiaries of federal medical service is unclear.

The recommendations of the report specify in particular a united medical administration to have control of Veterans Administration hospitals, general, post and station hospitals of the armed forces within the continental United States, the entire Public Health Service, nonmilitary hospitals in the Canal Zone, and hospitals of the Food and Drug Administration. At its head should be "the ablest health and medical administrator obtainable," who would be appointed by the President and confirmed by the Senate.

Congressional action should define clearly those who are entitled to the benefits of Government care, and a survey should be made to determine the amount of federal assistance that is necessary for medical and health education.

Research, preventive medicine and public health—all of which are factors in the prevention of disease—should be given high priority. The best way of lowering the costs of medical care is to decrease the need for it.

Although the Commission was divided on this point, the consensus of opinion was in favor of an independent health agency at the present time, rather than one that would combine health, education and security. Such a combination, however, might be eventually desirable.

THE ADRENAL GLAND AND THE RHEUMATIC STATE

THE discovery by Hench and his collaborators^{1, 2} of the remarkably beneficial effect of a particular adrenocortical steroid (compound E or Cortisone) on the course of rheumatoid arthritis and rheumatic fever has been amply confirmed and must be classified as one of the significant achievements of modern medicine. Elsewhere in this issue of the *Journal* Thorn and his associates show that stimulation by anterior pituitary adrenocorticotrophic hormone (ACTH or ACTARMOUR) is equally effective by inducing the secretion of substances similar to compound E by the patient's own adrenal glands. The striking improvement in symptomatology and the establishment of an almost euphoric state in patients with rheumatoid arthritis or rheumatic fever far surpasses the effects of any of the conventional drugs now employed. It is already apparent, however, that withdrawal of therapy may precipitate recurrence of symptoms, particularly in patients with rheumatoid arthritis. This suggests that the primary cause of the rheumatic state is not affected by adrenal-hormone therapy, although the manifestations of the disease are completely abolished.

Studies on the state of adrenocortical function in patients who subsequently respond to treatment do not permit one to postulate *absolute* adrenocortical insufficiency as a prerequisite to the development of the rheumatic state. In fact, rheumatoid arthritis is rarely seen among untreated patients with Addison's disease. The very large dose of Cortisone (100 mg daily) required to initiate a therapeutic response may lead to the development of Cushing's

syndrome, a manifestation of adrenocortical overactivity, when the drug is administered for periods exceeding two weeks. The effective therapeutic dose thus exceeds the quantity produced by the adrenal glands under normal circumstances. This suggests that the effect in rheumatoid arthritis represents a pharmacologic action of the hormone. The presence of factors inhibiting the normal physiologic action of Cortisone in patients with rheumatic disease must also be considered.

The rapid and dramatic improvement that follows therapy forms a unique opportunity to investigate the pathogenesis of these hitherto baffling disorders. The rapidity with which initial improvement is noticed (often within six hours of the injection) raises interesting speculation concerning the mechanism by which the course of such persistent and chronic disorders as rheumatoid arthritis, disseminated lupus and rheumatic fever is modified.

It is apparent that, in contrast to Cortisone, improvement in these disorders with ACTH therapy presupposes the capacity of the patient's own adrenal glands to produce large quantities of hormone for prolonged periods. It is to be anticipated that under certain circumstances adrenocortical reserve might be low, and ACTH therapy hence would be relatively ineffective. With both drugs undesirable side effects resulting from excessive adrenal-hormone therapy must be anticipated. The adrenal glands of patients treated with Cortisone will presumably undergo compensatory atrophy during the period of therapy, whereas with ACTH treatment there will be marked hypertrophy and hyperplasia. With both drugs the function of the anterior pituitary body, at least in the production of ACTH, will be depressed. It appears that the adrenal gland and pituitary body return to their normal state within a few days of the discontinuance of therapy.

To date Cortisone and the closely related 17-hydroxy-corticosterone or compound F have proved to be by far the most effective antirheumatic agents, making them practically specific. Cortisone, being derived from bile acids by a twenty-four-step chemical procedure, is limited in amount and of necessity very expensive. An active search for other sources of more immediate precursors of Cortisone has led

REPORT OF THE HOOVER COMMISSION REVIEWED

THE duties of the Commission on Organization of the Executive Branch of the Government, known as the Hoover Commission, were "to investigate activities of the Executive Branch with the objectives of limiting expenditures as far as possible consistent with proper performance of essential services, doing away with overlapping and duplication, consolidating similar services and abolishing unnecessary ones, and defining the limits of executive function"

An analysis of the report of the Committee on Medical Services of the Commission was presented at the annual meeting of the Massachusetts Medical Society by Professor Hugh R. Leavell of the Harvard School of Public Health and appears as the leading article in this issue of the *Journal*

When the report was first released it became immediately apparent that the federal Government was spending far too much money on medical and public-health operations, most of the expenditures being made by the Veterans Administration, the armed forces and the Federal Security Agency. The taxpayer may well be aghast at the medical bill of \$1,250,000,000, incurred in 1948, even accustomed as he has become to governmental extravagance.

The chief present weaknesses in the health services are in the medical-care program rather than in public health and research. This consists of competition between agencies for scarce personnel, wasteful construction of hospitals without over-all planning, and failure to utilize existing facilities to the best advantage. A lack of centralized responsibility for the over-all federal health plan has resulted in the competition among agencies for scarce medical and technical personnel and in hospital construction regardless of the plans or needs of other agencies or of state and local facilities. Construction costs range from \$20,000 to \$51,000 per bed, with voluntary hospital construction estimated at about \$16,000 per bed. The dollar has apparently two values — fifty cents to the average citizen, and a quarter when spent by the Government! The geographic location of Veterans Administration Hospitals has also been unwise, and the policy regarding beneficiaries of federal medical service is unclear.

The recommendations of the report specify in particular a united medical administration to have control of Veterans Administration hospitals, general, post and station hospitals of the armed forces within the continental United States, the entire Public Health Service, nonmilitary hospitals in the Canal Zone, and hospitals of the Food and Drug Administration. At its head should be "the ablest health and medical administrator obtainable," who would be appointed by the President and confirmed by the Senate.

Congressional action should define clearly those who are entitled to the benefits of Government care, and a survey should be made to determine the amount of federal assistance that is necessary for medical and health education.

Research, preventive medicine and public health—all of which are factors in the prevention of disease—should be given high priority. The best way of lowering the costs of medical care is to decrease the need for it.

Although the Commission was divided on this point, the consensus of opinion was in favor of an independent health agency at the present time, rather than one that would combine health, education and security. Such a combination, however, might be eventually desirable.

THE ADRENAL GLAND AND THE RHEUMATIC STATE

THE discovery by Hench and his collaborators^{1, 2} of the remarkably beneficial effect of a particular adrenocortical steroid (compound E or Cortisone) on the course of rheumatoid arthritis and rheumatic fever has been amply confirmed and must be classified as one of the significant achievements of modern medicine. Elsewhere in this issue of the *Journal* Thorn and his associates show that stimulation by anterior pituitary adrenocorticotrophic hormone (ACTH or ACTARMOUR) is equally effective by inducing the secretion of substances similar to compound E by the patient's own adrenal glands. The striking improvement in symptomatology and the establishment of an almost euphoric state in patients with rheumatoid arthritis or rheumatic fever far surpasses the effects of any of the conventional drugs now employed. It is already apparent, however, that withdrawal of therapy may precipitate recurrence of symptoms, particularly in patients with rheumatoid arthritis. This suggests that the primary cause of the rheumatic state is not affected by adrenal-hormone therapy, although the manifestations of the disease are completely abolished.

Studies on the state of adrenocortical function in patients who subsequently respond to treatment do not permit one to postulate *absolute* adrenocortical insufficiency as a prerequisite to the development of the rheumatic state. In fact, rheumatoid arthritis is rarely seen among untreated patients with Addison's disease. The very large dose of Cortisone (100 mg daily) required to initiate a therapeutic response may lead to the development of Cushing's

syndrome, a manifestation of adrenocortical overactivity, when the drug is administered for periods exceeding two weeks. The effective therapeutic dose thus exceeds the quantity produced by the adrenal glands under normal circumstances. This suggests that the effect in rheumatoid arthritis represents a pharmacologic action of the hormone. The presence of factors inhibiting the normal physiologic action of Cortisone in patients with rheumatic disease must also be considered.

The rapid and dramatic improvement that follows therapy forms a unique opportunity to investigate the pathogenesis of these hitherto baffling disorders. The rapidity with which initial improvement is noticed (often within six hours of the injection) raises interesting speculation concerning the mechanism by which the course of such persistent and chronic disorders as rheumatoid arthritis, disseminated lupus and rheumatic fever is modified.

It is apparent that, in contrast to Cortisone, improvement in these disorders with ACTH therapy presupposes the capacity of the patient's own adrenal glands to produce large quantities of hormone for prolonged periods. It is to be anticipated that under certain circumstances adrenocortical reserve might be low, and ACTH therapy hence would be relatively ineffective. With both drugs undesirable side effects resulting from excessive adrenal-hormone therapy must be anticipated. The adrenal glands of patients treated with Cortisone will presumably undergo compensatory atrophy during the period of therapy, whereas with ACTH treatment there will be marked hypertrophy and hyperplasia. With both drugs the function of the anterior pituitary body, at least in the production of ACTH, will be depressed. It appears that the adrenal gland and pituitary body return to their normal state within a few days of the discontinuance of therapy.

To date Cortisone and the closely related 17-hydroxy-corticosterone or compound F have proved to be by far the most effective antirheumatic agents, making them practically specific. Cortisone, being derived from bile acids by a twenty-four-step chemical procedure, is limited in amount and of necessity very expensive. An active search for other sources of more immediate precursors of Cortisone has led

to their discovery in an African strophanthus plant and a Mexican yam. ACTH is, at present, derived from the pituitary body of domestic animals, the hog in particular. Some 4000 hogs will yield enough ACTH to treat one patient for twenty days. In the present difficulty with totally inadequate supplies of Cortisone and ACTH for large-scale therapeutic use, the producers of these substances have adopted specific plans for the equitable distribution of the material.

Cortisone (Merck) is sold to competent investigators only after their specific requests to and acceptance by a committee appointed by the National Academy of Science. The requirements of the committee are such that the investigators must have adequate facilities for properly studying the over-all metabolic effects, mode of action and clinical influence of the hormone in various disease states. ACTH is distributed to competent investigators for the same purpose by the Armour Laboratories.

In the present search for other effective agents in the treatment of the so-called "collagen" diseases and in reviewing the older forms of treatment that have proved helpful in certain cases, one is constantly confronted with this question: Is the drug effective because of its specific pharmacologic action, or is it merely one of many agents capable of eliciting a nonspecific pituitary-adrenal response and thereby of increasing the level of circulating adrenocortical steroids temporarily? The studies of Selye et al.³ leave no doubt that a wide variety of stresses initiate a response that is characterized by the liberation of pituitary ACTH and secondarily adrenocortical hormone. Any agent or procedure capable of eliciting this reaction in a patient with rheumatoid arthritis must be considered potentially capable of initiating a profound change in the course of the disease. Unfortunately, it is usually not possible to obtain an excess of adrenal hormone for prolonged periods by nonspecific means because of the depressing effect of a high level of circulating adrenal steroids on further pituitary-ACTH production.

Although it is too early to evaluate the ultimate clinical usefulness of these drugs in the treatment of rheumatic disease, there is no doubt that investigation in this field of disease has been given a tremen-

dous stimulus. Furthermore, preliminary reports suggest that the usefulness of these hormones is not limited to the group of so-called "collagen" diseases, but that they have much more widespread value.

UNIPOLAR ELECTROCARDIOGRAPHY

ELECTROCARDIOGRAPHY is often said to be an empirical science, but it can hardly be termed static. The physician who labored long and hard to master the standard bipolar limb leads was not allowed to relax with his newly gained knowledge very long. The introduction of bipolar precordial leads into clinical practice, after much debate and in the face of considerable objection, made it necessary for him to continue to dig into the journals and newer textbooks in order to keep abreast of the field. Those who made the effort were not long in appreciating the great value of the innovation, particularly in the diagnosis of anterior myocardial infarction. As experience accumulated, the additional value of multiple precordial leads became apparent. As if this were not enough, the practice of taking bipolar leads was challenged, and the advantages to be gained by rendering one electrode indifferent were pointed out, originally by Wilson and later by Goldberger. Although some years have elapsed since Wilson introduced the technic, it has only recently begun to receive the attention it deserves.

The need for a more precise electrocardiographic method for determining relative right or left ventricular predominance has long been recognized. Inextricably bound up with the same problem is the question of how best to determine the position of the heart electrocardiographically, since, in many cases, enlargement of a ventricle greatly influences the position of the heart. With standard limb leads alone, there may be no way to differentiate changes due to alteration in the position of the heart.

and those due to a damaged myocardium Goldberger, by the use of augmented unipolar leads and by his emphasis on unipolar limb leads, has shown how unipolar electrocardiography may be the key to many problems involving changes in the position of the heart or enlargement of a ventricle, or both.

It is still too early to advocate the routine clinical use of unipolar limb leads, augmented or otherwise. Unipolar chest leads are used routinely by many electrocardiographers, and some knowledge of them is rapidly becoming essential. In the diagnosis of myocardial infarction it is doubtful that unipolar electrocardiography possesses any great advantage over bipolar methods. In anterior infarcts the standard bipolar limb leads and multiple precordial leads, either unipolar or bipolar, are likely to provide information of diagnostic value, particularly if serial studies are carried out. For the diagnosis of posterior infarcts the physician must still lean heavily on the standard bipolar limb leads. It seems likely, however, that when satisfactory standards for unipolar leads are developed and as experience grows, the technic may find a permanent place in the list of useful electrocardiographic procedures. The specific value of augmented unipolar leads is yet to be defined, but Goldberger's interpretation of unipolar limb leads should be borne in mind whenever information concerning the position of the heart is needed. The further development of unipolar electrocardiography is well worth watching by physicians interested in cardiology.

NATIONAL BIRTH STATISTICS

A RELEASE from Federal Security Administrator Oscar R. Ewing discloses that "a greater proportion of births in the United States were delivered in hospitals or institutions in 1947 than in any previous year on record."

The number of registered live births during 1947 rose to a peak of 3,699,940, with the proportion occurring in hospitals reaching a new high of 84.8 per cent.

Births attended by physicians were higher in urban than in rural areas, 98.0 per cent and 90.3 per cent respectively, and markedly higher in white (98.5 per cent) than in nonwhite (67.4 per cent).

populations. Deliveries in Connecticut, Nebraska, New Hampshire and the District of Columbia were attended by physicians in 100 per cent of the cases, although in the District of Columbia, interestingly enough, 10 per cent of the births are also listed as having been attended by midwives. In Massachusetts and Vermont 99.9 per cent of cases were attended by physicians with no midwives participating in any case. In Mississippi physicians attended 61.4 per cent of the deliveries, midwives caring for the remainder.

It will be seen by our weekly report that the cholera is no longer in the city as an epidemic. Of the 5 deaths from the disease last week, 3 were individuals just arrived from other places. Although its ravages here have been light compared with those of some other places, yet it has numbered over 600 victims during the three months of its prevalence, and has increased the mortality of the city, during some weeks, more than a hundred per cent above the weekly average.

Boston M & S J, October 3, 1849

MASSACHUSETTS MEDICAL SOCIETY

DEATHS

HARTNETT — John H. Hartnett, M.D., of Worcester, died on May 10. He was in his seventy-fourth year.

Dr. Hartnett received his degree from Tufts College Medical School in 1911. He was affiliated with Belmont Hospital and St. Vincent Hospital. He was a fellow of the American Medical Association.

His widow, a son, two daughters, a brother and three sisters survive.

LAMBERT — John H. Lambert, M.D., of Lowell, died on September 10. He was in his seventy-fourth year.

Dr. Lambert received his degree from Boston University School of Medicine in 1899. He was formerly senior-surgeon at Lowell General Hospital and consulting roentgenologist at Bedford Veterans Administration Hospital. He was a former president of Middlesex North District Medical Society and was a member of the New England Roentgen Ray Society and the American Roentgen Ray Society and a fellow of the American College of Surgeons and American Medical Association.

His widow, three daughters, two sons and nine grandchildren survive.

MASON — Robert L. Mason, M.D., of Wellesley, died on September 20. He was in his fifty-third year.

Dr. Mason received his degree from Harvard Medical School in 1922. He was formerly chief of the surgical staff at Cushing General Hospital and a member of the staff of the Lahey Clinic. He was a fellow of the American College of Surgeons and the American Medical Association.

His widow, a son and three daughters survive.

The need for a more precise electrocardiographic method for determining relative right or left ventricular predominance has long been recognized. Inextricably bound up with the same problem is the question of how best to determine the position of the heart electrocardiographically, since, in many cases, enlargement of a ventricle greatly influences the position of the heart. With standard limb leads alone, there may be no way to differentiate changes due to alteration in the position of the heart.

consequent immunity alone is desired, however, only one specimen need be submitted

For information regarding serologic diagnosis of other virus infections, the Laboratory should be consulted directly (telephone, Jamaica 4-5440). It should be noted that none of these tests will assist in confirming diagnosis during the early acute stage. They are useful mainly in making diagnosis in retrospect. Since funds for these services are limited, physicians should send specimens of real diagnostic importance only.

UNUSUAL SEROLOGIC TESTS

It is not practical for a state laboratory to attempt to perform certain unusual tests requested by physicians infrequently and at irregular intervals. It has been the practice to forward such specimens to one of the laboratories of the United States Public Health Service.

Some of the unusual serologic tests formerly performed at the National Institutes of Health, Bethesda, Maryland, are now being done entirely at the Communicable Disease Center in Georgia. These are amebiasis, trichinosis, echinococcus and leptospirosis. These specimens should hereafter be sent to Immunology-Serology Laboratory, Communicable Disease Center, United States Public Health Service, Chamblee, Georgia.

Serologic tests for trypanosomiasis, schistosomiasis, filariasis, leishmaniasis and toxoplasmosis should still be sent to Laboratory of Tropical Diseases, National Institutes of Health, Bethesda 14 Maryland.

DISCONTINUANCE OF DISTRIBUTION OF VARIOUS DRUGS

The Massachusetts Department of Public Health has discontinued the distribution of nearsphenamine, sulfarsphenamine and sulfathiazole tablets. However, the distribution of Mapharsen and bismuth subsalicylate in oil to private physicians for the treatment of patients with syphilis will be continued.

MISCELLANY

MASSACHUSETTS ASSOCIATION OF SCHOOL PHYSICIANS

At a meeting of the interim committee of the Massachusetts Association of School Physicians, attended by Drs. Mary Moore Beatty, Antonio Milone, Anthony H. Nikiel, Alan Poole, Honoria K. Shine and Allan R. Cunningham, chairman, and held on September 11 at Hotel Sheraton, Worcester, a draft of the proposed constitution was completed.

Copies of this draft will be mailed to each of the 620 school physicians of Massachusetts, and further organization will proceed by meetings of school physicians in each of the eight health districts of the Commonwealth.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Manual of Clinical Laboratory Methods. By Opal E. Helper, Ph.D., M.D., associate professor of pathology, Northwestern University Medical School, director of the clinical laboratories, Montgomery Ward Clinics and Passavant Memorial Hospital, and consultant in clinical pathology, Children's Memorial Hospital, Chicago. With a foreword by James P. Simonds, Ph.D., M.D. Fourth edition. 4°, cloth, 387 pp. with 36 illustrations. Springfield, Illinois: Charles C. Thomas, 1949. \$8.50.

The first edition of this standard work was published originally in 1935. The soundness and popularity of the manual is attested by the need of this fourth edition. The book is intended primarily for use in the teaching of medical students and laboratory technicians, and is not designed as a textbook on clinical pathology. In most instances only one method is included for each determination, and the procedures are given in outline form so that they may be followed easily in the laboratory. There is a comprehensive index, and the book is well published. It should prove useful to the laboratory worker.

The Psychoanalytic Reader: An anthology of essential papers with critical introductions. Volume I. Edited by Robert Fliess, M.D. 8°, cloth, 392 pp. New York: International Universities Press, Incorporated, 1948. \$7.50.

This volume, the first in a projected series, comprises important contributions selected from the literature of the period beginning with 1909 and extending to date. The material is divided into five parts: clinical, theory, miscellaneous uncollected papers of Karl Abraham, and references by Freud (to six publications of other authors). The part on theory includes the articles on female and preoedipal sexuality. There should have been an index, if only of authors. The series should be in all collections on the subject.

Child Psychiatry. By Leo Kanner, M.D., associate professor of psychiatry, Johns Hopkins University School of Medicine, and director, Children's Psychiatry Service, Johns Hopkins Hospital. With prefaces by John C. Whitehorn, M.D., Henry Phipps Professor of Psychiatry, Johns Hopkins University School of Medicine, Adolf Meyer, M.D., LL.D., and Edwards A. Park, M.D. Second edition. 4°, cloth, 752 pp. Springfield, Illinois: Charles C. Thomas, 1949. \$8.50.

This standard work was published first in 1935 and reprinted four times from 1937 to 1947. In this second edition the author has completely rewritten his book, incorporating the great advances made in the subject during the past thirteen years. This second edition was published simultaneously in the United States, Great Britain and Canada, and in Spanish in Chile. The text is divided into four parts: history, basic orientation, clinical considerations, and phenomenology, again subdivided into three sections, including personality problems arising from physical illness, psychosomatic problems and problems of behavior. The material is well arranged and well written and documented throughout with references to the appropriate literature. There are indexes of authors and subjects. The printing is well done with a beautiful, large type. The book is recommended for all medical and sociologic libraries and to psychiatrists and pediatricians.

NOTICES

ANNOUNCEMENT

Dr. Francis A. Walsh announces the removal of his office to 1826 Centre Street, West Roxbury.

NOTES FROM THE MEDICAL EXAMINER

DETERMINATION OF THE BLOOD GROUPS OF DRIED BLOOD STAINS

The antigens A and B, which determine the classic blood groups, are relatively stable substances. Therefore, it is possible to determine their presence in dried blood stains and thus indirectly to determine the group of blood that produced the stain. The principle of this technic is as follows:

One allows a mixture of anti-A and anti-B reagent to react with the stain. The quantities of agglutinins in the reagent are carefully adjusted so that a stain that contains only a small amount of A, for example, will remove all the anti-A. The anti-B is similarly adjusted. These amounts are determined by preliminary tests on stains of known groups. The reaction is usually carried out with about 1 sq. cm. of material, such as stained cloth, finely cut up with scissors and mixed with the anti-A and anti-B reagent in a test tube. After this mixture has been allowed to stand overnight, preferably with occasional mixing during the interval, a drop of the liquid is taken off with a wire loop and is tested with Group A cells. A similar preparation is made with a loopful from the mixture and Group B cells. If Group A cells are agglutinated, but Group B cells are not, one may conclude that the following sequence of events took place: the anti-B in the reagent was neutralized by the B substance contained in the stain and thereby prevented from exerting further action against Group B substances so that when the supernatant was tested against Group B cells, no reaction took place. The anti-A in the liquid, on the other hand, since it met no Group A substance, was not used up and was still active in the supernatant liquid.

The volume of the reagent applied to the stain should permit an excess of two or three loopfuls; the concentration of the reagent should be such that anti-A and anti-B are approximately 1:8 of human serum of 1:64 titer.

During the test of the supernatant, which is usually carried out on a microscope slide, provision must be made to prevent evaporation. This can be done by a moist chamber or a sealed hanging-drop preparation.

The possible reactions are as follows: the stain may remove neither anti-A nor anti-B or may remove one or the other, or both. In each case the diagnosis of the blood group of the stain is shown: Group O, no agglutinin removed; Group A, anti-A removed; Group B, anti-B removed; Group AB, anti-A and anti-B removed.

In order that the highest confidence may be placed on the test it is extremely desirable that at the same time stains of known group and of similar age be tested under similar conditions. When all reagents are suitably chosen, and the tests are

properly conducted, stains no larger than 1 cm. in area may be identified. Age alone, in the absence of putrefaction, is not a serious limitation for evidence has been put forward that stains for years old have been correctly identified.

Another desirable control is to test the material away from the stain—cloth, paper or whatever it may be—to demonstrate the absence of specific or nonspecific power to remove either anti-A or anti-B agglutinin from the reagent.

It is possible to confirm a grouping by testing recent stain for the agglutinins anti-A or anti-B, or both. The finding of both in a stain thought to be Group O is a welcome confirmation. These tests are best carried out by the "crusts" technic of Lattes. However, the agglutinins deteriorate more rapidly than the agglutinogens.

WILLIAM C. BOYD, PH.D.

Professor of Immunochemistry, Boston University School of Medicine

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

SEROLOGIC TESTS FOR VIRUS DISEASES

The Department has previously announced to physicians its facilities for performing a limited number of serologic tests for certain virus diseases, such as influenza A and B, mumps and lymphocytic choriomeningitis. To this list is now added tests for cold agglutinins, useful in the diagnosis of atypical pneumonia, as well as complement-fixation tests for the more common encephalitides.

Specimens should be submitted in the Department's special outfit, and accompanied by properly filled out forms entitled "Request for Serologic Tests for Certain Virus Diseases." The "agglutinations-cultures outfit" to be used (previously called the "undulant-fever outfit") and the special forms to be filled out may be obtained from local boards of health, or directly from the Massachusetts Department of Health, Bacteriological Laboratory, 281 South Street, Jamaica Plain 30.

In each suspected case, two aseptically collected 4-cc. serum specimens are required, the first taken as soon as possible after the onset of the disease, and the second ten to fourteen days later (six weeks or more after onset for neutralization tests in cases of lymphocytic choriomeningitis). If facilities for separation of serum are not available, 10 cc. of clotted blood for each specimen may be substituted if it is mailed to the laboratory at once. *Since positive diagnosis can be made only if a rise in antibody titer is demonstrated (fourfold or greater is considered significant) during the course of the illness, two specimens must be sent.* Tests for diagnosis, therefore, will be run only on paired specimens. If information regarding past mumps infection and

HIRSCHSPRUNG'S DISEASE A NEW CONCEPT OF THE ETIOLOGY*

Operative Results in Thirty-Four Patients

ORVAL SWENSON, M.D. † HAROLD F. RHEINLANDER, M.D., ‡ AND ISRAEL DIAMOND, M.D. §

BOSTON

CONGENITAL megacolon has been recognized as a clinical entity for over a hundred years. Many reports were written on the subject before Hirschsprung¹ published his classic description of the disease in 1888. His presentation included the clinical study and autopsy findings of 2 patients with megacolon and was more complete than anything previously recorded. Subsequently, scores of papers have been written on the etiology and treatment of megacolon.

The numerous theories set forth in these publications may be divided into four categories and summarized as follows:²

The disease is due to congenital lesions in the dilated colon. Hirschsprung¹ thought that both the hypertrophy and the dilatation of the bowel were congenital. Miva⁴ believed that although the dilatation was congenital the hypertrophy was secondary and occurred after birth.

The cause is a mechanical obstruction that produces the dilated and hypertrophied colon. Marfan⁵ postulated that an elongated and looped colon could result in the clinical and pathological picture. Treves⁶ thought that the condition was due to an actual mechanical obstruction and that the dilatation and hypertrophy could be explained on this basis.

The disease may be due to infection of various types. Among the proponents of this theory were Walker and Griffiths,⁷ who suggested that chronic colitis was the beginning pathologic change initiating a chain of events that finally resulted in Hirschsprung's disease.

The condition is due to a neurogenic imbalance. Most students of the disease during the past two decades have suggested theories that postulate

some type of deficiency of nerve supply to the bowel. In 1900 Fenwick,⁸ who was the first of this group, stated that spasm of the anal sphincter resulted in dilatation of the colon. Hawkins,⁹ in 1907, labeled the disease "neuropathic dilatation and hypertrophy of the colon." He suggested that a neuromuscular defect existed in one segment of the colon, and that intestinal contents had difficulty in passing through this area. In 1926 Fraser¹⁰ wrote about malfunction of the colon associated with defective relaxation of the sphincter due to abnormalities in the involuntary nervous system. Wade and Royle,¹¹ in 1927, agreed that the disease was due to a similar mechanism caused by an overactive sympathetic nervous system; they performed lumbar sympathectomy to obviate sympathetic overstimulation. Martin and Burden,¹² in the same year, claimed that "rectosigmoid sphincterismus" due to derangement of intrinsic nerve supply caused a partial intestinal obstruction resulting in the disease. In 1930 Scott and Morton¹³ showed that spinal anesthesia produced evacuation of the colon in patients with Hirschsprung's disease. This was accepted as evidence that overactivity of the sympathetic nervous system existed.

Considerable differences of opinion also exist about treatment. The methods of therapy employed at present may be divided into three groups: attempts to control the disease by medical management, surgical treatment consisting of resection of parts or all of the dilated and hypertrophied colon, and section of the sympathetic pathways to part or all of the colon.

Medical treatment consists of special diets, laxatives and enemas, and various drugs that influence intestinal motility. Success has been reported with such drugs as Mecholyl bromide¹⁴ which tend to increase intestinal peristalsis. Equally good results have been reported with syntropan.¹⁵ These two drugs presumably have opposite effects, the former being a parasympathomimetic and the latter a

LAY MEETING ON DIABETES DETECTION

A lay meeting on diabetes detection will be held in the John Hancock Hall of the new John Hancock Building in Boston on October 10. Sponsoring organizations are the New England Diabetes Association, the Committee on Diabetes of the Massachusetts Medical Society, and the American Diabetes Association.

The following outstanding investigators in the field of diabetes will speak: Dr. H. C. Hagedorn, of Copenhagen, Denmark, the discoverer of protamine insulin; Dr. Charles H. Best, winner of the Nobel Medal and co-discoverer of insulin; and Dr. Howard F. Root, of Boston.

Announcement of gifts from Denmark and Canada for the establishment of research foundations in the United States will be made at the meeting.

BOSTON CITY HOSPITAL OFFICERS' ASSOCIATION

The second in a series of Tuesday evening lectures sponsored by the Boston City Hospital House Officers' Association will be held in the New Cheever Amphitheater of the Dowling Building, Boston City Hospital, on Tuesday, October 11, at 7 p.m. Dr. Charles P. Bailey, associate professor of surgery, Hahnemann Medical College, Philadelphia, will speak on the subject "Commisurotomy for Mitral Stenosis." Drs. Laurence B. Ellis, Dwight E. Harken, and John W. Strieder will lead the discussion.

All interested persons are invited to attend.

NEW ENGLAND SOCIETY OF ANESTHESIOLOGISTS

A regular meeting of the New England Society of Anesthesiologists will be held in the Auditorium of Building A, Boston University School of Medicine, on Tuesday, October 11, at 8 p.m.

Dr. Seymour S. Kety, professor of clinical physiology, University of Pennsylvania School of Medicine, will speak on the subject "Physical and Physiologic Factors Regulating the Uptake of Anesthetic Gases."

NEW ENGLAND VENEREAL DISEASE CONTROL CONFERENCE

The New England Venereal Disease Control Conference will be held in the Gardner Auditorium, State House, Boston, on Wednesday, October 12.

PROGRAM

Morning Session (10 00 a.m. to 12 00 noon)

The Effectiveness of the Multiphase Screen-Testing Program as a Syphilis Case Finding Mechanism

Funds for Syphilis-Control Activities in the Light of a Consistently Declining Reported Morbidity

Evaluation of American Venereal-Disease-Control Activities

Interstate Premarital Regulations and Standard Certificate — A Progress Report

Promiscuity — A Psychiatric Approach

Afternoon Session (2 00-4 00 p.m.)

Newer Experimental Treatment Schedules of Syphilis

The Immobilization Test of *Treponema pallidum* and Practical Application

The Management of Neurosyphilis

Nonspecific Urethritis

The Present-Day Treatment of Syphilis

MASSACHUSETTS CHAPTER, AMERICAN ACADEMY OF GENERAL PRACTICE

The annual meeting and fall clinical program of the Massachusetts Chapter of American Academy of General Practice will be held in Boston on October 19. The morning program will be held at the Massachusetts General Hospital, with medical and surgical clinics by the staff of the hospital. The luncheon, afternoon lecture program and banquet will be held at Hotel Puritan. Mr. Mac F. Cahal, executive secretary of the American Academy of General Practice, Kansas City, will be the speaker.

CONFERENCE OF PROFESSORS OF PREVENTIVE MEDICINE

The annual meeting of the Conference of Professors of Preventive Medicine will be held in New York City on October 24. Luncheon and afternoon sessions will be held in Parlor 1, Hotel Statler. Dr. David D. Rutstein, of Boston, is secretary.

PEDIATRIC SEMINAR FOR PHYSICIANS AND GENERAL PRACTITIONERS

A pediatric seminar for pediatricians and general practitioners will be held on November 23 and thereafter every second and fourth Wednesday of the month at 7 p.m. in Amphitheater 3A of the White Building, Massachusetts General Hospital, by the staff of the Children's Medical Service, Burnham Memorial Hospital for Children, Massachusetts General Hospital.

those which ordinarily follow chronic, low, partial colonic obstruction. Severe constipation and obstipation are the presenting complaints. Distention, audible and visible peristalsis, cramps and vomiting occur in varying degrees. Large fecal impactions are frequently present in the left side of the colon, whereas the rectal ampulla remains empty. Hirschsprung¹ commented specifically on this finding in his paper. Patients are relieved by colostomy above the area of malfunction, within three or four months dilatation of the colon largely disappears, and hypertrophy diminishes. However, if the colostomy

sigmoid. These important changes in the rectum and rectosigmoid are missed if the lower colon is flooded with too much barium (Fig 1).

Resection of the rectum and rectosigmoid in 34 patients has resulted in 1 postoperative death and in what appears to be complete cure in the remaining 33 patients. This is accomplished by a special operative technic that preserves the anal sphincter.²⁷⁻²⁸ These patients have been followed for periods up to two years. Re-examination by barium enema has demonstrated return of the colon to approximately normal size and contour by the third

is closed the syndrome recurs, but reopening of the colostomy again provides relief.

Neuhauser²⁸ was the first to demonstrate by roentgenograms and to attach significance to a narrow segment of rectosigmoid distal to the dilated sigmoid in Hirschsprung's disease. He described this for the first time four years ago and has subsequently demonstrated it in 40 patients with congenital megacolon. This lesion, which Neuhauser and we consider pathognomonic of Hirschsprung's disease, is at times difficult to demonstrate. He recommends that only a small amount of barium should be injected while the patient is being examined under the fluoroscope in an oblique position. One can then observe the narrow, irregular rectum and rectosigmoid distal to the markedly dilated

postoperative month (Fig 2). More important, post-evacuation films show essentially normal emptying of the colon. Postoperatively, these patients are on normal diets and do not require laxatives, enemas or drugs.

The study of colonic function in these patients would add materially to knowledge of this disease. We have conducted a series of colonic-motility studies, using a multiple balloon technic.²⁹⁻³¹

STUDY OF COLONIC PERISTALSIS IN HIRSCHSPRUNG'S DISEASE

The apparatus used in recording motility was patterned after the apparatus used by Chapman.³¹ It consisted of three ink-writing manometers, each attached by a long catheter to a balloon. Each

parasympathetic depressant drug. Mild cases of Hirschsprung's disease can be controlled medically for long periods, but in severe forms these measures fail.

The second method consists of resection of parts or all of the dilated and hypertrophied bowel.^{16, 18} This procedure is based on the theory that the seat of the disease is the enlarged portion of the colon. Resection is frequently followed by recurrence proximal to the line of resection.^{17, 19} This experience

sults in some patients, there are cases of complete failure to alter the course of the disease.

Finally, several clinics have treated the disease by interruption of the sympathetic pathways to part or all of the colon.^{11, 13, 21-26} This approach was originated by Wade and Royle.¹¹ In 1930 Scott and Morton¹³ described the effects of spinal anesthesia on patients with megacolon. In some clinics evacuation following spinal anesthesia has been considered an indication for lumbar sympathectomy. It is

A

B

FIGURE 1. Roentgenograms of a Patient with Hirschsprung's Disease

A shows the bowel filled with barium in a routine manner. (Note the enlargement of the sigmoid colon and rectosigmoid, which might lead to the erroneous conclusion that the colonic dilatation extends down to the anus.)
B demonstrates the use of a special technique (in the same patient) in which small amounts of barium are instilled slowly into the rectum. (Note the lower segment of bowel, which is narrow and irregular and does not relax during the period of observation, the bowel lumen abruptly expands above this area into the dilated segment.)

coincides with what has been observed in this clinic.²⁰ A total colectomy with ileosigmoidostomy is advocated by some surgeons,¹⁷ even though only a portion of the colon seems to be involved. However, after removal of the entire colon, the ileum has been observed to undergo dilatation and hypertrophy, with recurrence of symptoms. Two patients under our observation, a few months after colectomy and ileosigmoidostomy, showed all the symptoms and signs of Hirschsprung's disease owing to tremendous dilatation of the ileum. In one of these patients an ileostomy was subsequently performed, with complete relief of symptoms and reversal of the changes in the ileum. The second patient, in whom an ileostomy was not performed, succumbed to his disease and at autopsy was found to have marked hypertrophy and dilatation of the terminal ileum. Although colectomy gives satisfactory clinical re-

sults, however, that sympathectomy does not reproduce the physiologic effect of spinal anesthesia. Some clinics are treating congenital megacolon by unilateral or bilateral lumbar sympathectomy. Presacral, para-aortic and inferior mesenteric chain resections may be combined with bilateral lumbar sympathectomy and splanchnicectomy.²⁵ The follow-up results of these procedures have not been uniformly satisfactory.

Recently, Swenson et al.^{27, 28} have presented evidence supporting their contention that congenital megacolon is due to malfunction of the rectosigmoid that results in partial colonic obstruction. This obstruction accounts for the dilatation and hypertrophy of the colon, which retains peristaltic function. There is much evidence to support this concept of the etiology of congenital megacolon. The signs and symptoms of Hirschsprung's disease are

those which ordinarily follow chronic, low, partial colonic obstruction. Severe constipation and obstipation are the presenting complaints. Distention, audible and visible peristalsis, cramps and vomiting occur in varying degrees. Large fecal impactions are frequently present in the left side of the colon, whereas the rectal ampulla remains empty. Hirschsprung¹ commented specifically on this finding in his paper. STUDY OF COLONIC PERISTALSIS IN HIRSCHSPRUNG'S DISEASE

The apparatus used in recording motility was patterned after the apparatus used by Chapman.³¹ It consisted of three ink-writing manometers, each attached by a long catheter to a balloon. Each

balloon was filled with 10 cc of air, and pressure changes were recorded on a kymograph

In 5 patients with Hirschsprung's disease (Group I) colostomy had been performed as a preliminary step in resection of the rectum and rectosigmoid. In this group a Levine tube was introduced through the colostomy and was passed with fluoroscopic aid into the rectosigmoid. A sigmoidoscope was used to bring the tube out through the anus. Balloons attached to separate catheters were then tied to the Levine tube at intervals. By gentle traction the whole apparatus could be positioned so that one balloon was in the splenic flexure, a second in the

after the ingestion of food, and were of equal amplitude in each area, as recorded by the three manometers. Between large waves there were smaller waves, which were recorded from all areas of the bowel tested. The smaller contractions were assumed to be those of segmentation.³²

The recordings from the patients with congenital megacolon exhibited a different pattern (Fig 3B). The two proximal balloons in the splenic flexure and lower descending colon showed peristalsis, as did the controls. This supports our contention that the dilated and hypertrophied colon retains peristaltic function. The recordings from the balloon in the

FIGURE 3

A = Tracings from a control patient with colostomy. The upper line records activity of the balloon in the splenic flexure. The middle line records from the balloon in the descending colon, and the lower tracing is from the balloon in the rectosigmoid. Tracings progress from left to right. Note the appearance of large waves progressing from the upper to the lower balloons. Smaller contractions are also present.

B = Tracings from a patient with Hirschsprung's disease in whom a preliminary colostomy had been performed. The recordings are from balloons in the same relative positions as the control patient in Fig 3A. Note that the large waves, which are tracings from the upper two balloons in the dilated and hypertrophied bowel, do not progress into the narrowed rectosigmoid. Small, unassociated waves are recorded from the lower balloon in the narrow lower segment.

descending colon and a third in the narrow portion of the rectosigmoid. The balloons were then inflated and tracings were made. Two patients who had had an intussusception requiring resection and ileo-transverse colostomy of the Mikulicz type were used as controls.

Three patients with Hirschsprung's disease (Group II), in whom colostomy had not been performed, were studied by the insertion of two balloons through the anus. One of the balloons was positioned in the sigmoid and the other in the narrow rectosigmoid. Postoperative as well as preoperative studies were performed in this second group of patients. Control tracings were obtained in a similar manner from 2 patients with normal colons. In all these studies food was given to stimulate colonic peristalsis.

RESULTS OF STUDIES ON COLONIC PERISTALSIS

Group I

Recordings from the control patients with colostomies showed progression of the propulsive peristaltic wave from the transverse colon to the anus (Fig 3A). These waves appeared in groups, usually

narrow rectosigmoid were entirely different, no peristaltic wave was recorded from this site. As compared to the controls, there was a larger rise in the height of the recording baseline when 10 cc of air was injected into the balloon. The higher baseline, indicating increased tonus, changed little if at all during the period of observation, and was interpreted as failure of relaxation of this segment of bowel. In 2 of the patients with Hirschsprung's disease there were no changes whatever in intraluminal pressure from the rectosigmoid segment. In the other 3 patients with the disease there was a rhythmic series of segmental contractions of low amplitude in this area, which was totally dissociated from the peristaltic waves in the descending colon.

Group II

Recordings from the normal control patients with balloons in the sigmoid and rectosigmoid demonstrated forceful peristaltic waves, which progressed to the anal sphincter. In 3 patients with Hirschsprung's disease who had had no preliminary colos-

tomy, peristaltic waves were recorded from the dilated sigmoid, but these waves did not enter the narrow rectosigmoid. No contractions whatever were recorded from the lower balloon in 1 of these patients. In another, slight rhythmic segmental contractions were recorded from the balloon in the narrow segment. These contractions were independent of the powerful contractions in the dilated sigmoid. In the third subject normal contractions, not related to sigmoid peristalsis, were recorded from the rectosigmoid. Postoperatively, this group yielded tracings identical with those of the normal controls. Powerful peristaltic waves were recorded, which now progressed to the anus.

Attempts have been made a number of times to relate the pathogenesis of congenital megacolon to abnormality of the myenteric plexus. Dalla Valle,³³ in 1920, described a case of congenital megacolon in which almost no myenteric plexuses were seen in the sigmoid and ascending colon. Ganglion cells were present in the hepatic flexure and transverse colon. Robertson and Kernohan³⁴ described absence and deformity of myenteric ganglion cells in a case of congenital megacolon. Tiffin, Chandler and Faber³⁵ reported localized absence of myenteric plexus in the undilated sigmoid; ganglion cells were normally distributed in the proximal, dilated colon. Recently, Zuelzer and Wilson³⁶ made similar observations in cases of congenital intestinal obstruction in infancy. Both the latter studies suggest that some cases of congenital megacolon are due to agenesis of myenteric plexus in the lower bowel.

A survey of the distribution of myenteric ganglion cells was made in 7 of the cases reported. The excised colonic segments were examined by the removal of five longitudinal strips from the entire length of each segment. The strips were divided into consecutive numbered blocks approximately 2.5 cm. in length and sectioned parallel to their long axis. At selected intervals consecutive numbered blocks were taken along the short axis of the bowel. Formalin-fixed and Klotz-fixed tissues were used, and sections stained with hematoxylin and eosin. When indicated, blocks were serially sectioned at intervals of 10 microns to confirm the absence of ganglion cells.

When ganglion cells are present the sections from blocks taken from different areas of a given circumference show that the myenteric plexus forms a fairly continuous sheet between the two layers of muscle. Zuelzer and Wilson³⁶ point out that ganglion cells were found in all sections at every level in 10 normal colons. Every section of colon taken from random areas in 50 consecutive autopsies in our files showed ganglion cells.

Five of the bowels presented a similar pattern in ganglion-cell distribution. The myenteric plexus was present in the dilated proximal portion and absent in the distal narrow portion. The absence of ganglion cells was not closely related to the level of

narrowing of the lumen. Frequently, the cells disappeared proximal to this. One case showed no ganglion cells in any portion of the specimen. In another, exhibiting strong independent rectosigmoid contractions, the pattern was different. Ganglion cells were present throughout the distal narrow segment. Proximal to this in the dilated segment a zone measuring 4 or 5 cm. in length was found devoid of ganglia. Above this, ganglion cells were again present.

The distribution of the ganglion cells, when correlated with the motility studies, suggests that absence of the peristaltic-wave progression may be due to absence or abnormal distribution of the myenteric plexus in a segment of the colon. It is not suggested that this occurs in all cases of congenital megacolon.

CONCLUSIONS

In performing motility studies we have observed that complete quiescence of the normal colon may persist for as long as six hours. A simple method for initiating normal contractions is the ingestion of food. Tracings from a single balloon are of no significance, since no record of peristaltic progression is obtained. In a patient with Hirschsprung's disease, only a multiple-balloon technic will demonstrate that propulsive waves are present in one part of the colon and absent in another.

In the past, the emphasis on Hirschsprung's disease has been directed to the dilated and hypertrophied colon. It is our contention that the primary lesion rests in the distal, nondilated segment, despite the fact that grossly this area appears normal. We have demonstrated in control patients that groups of strong peristaltic waves progress from the transverse colon to the anus. In 8 patients with Hirschsprung's disease we have recorded strong peristaltic waves in the dilated and hypertrophied colon. In 5 patients progression of the peristaltic waves along the enlarged segment was evident. In none of the 8 patients with Hirschsprung's disease did the peristalsis enter the narrow distal segment, which did exhibit increased tonus.

We believe that the absence of normal propulsive waves in the rectum and rectosigmoid constitutes a physiologic defect that results in chronic obstruction. This malfunctioning segment is identical with the narrow, irregular bowel visualized by roentgenograms. There appears to be a correlation between the absence of ganglion cells in areas of the rectosigmoid and the physiologic defect.

Removal of the narrow, irregular rectum and rectosigmoid by a special surgical technic in 34 patients has resulted in 1 postoperative death and what appears to be complete cures in 33 patients. As early as three months postoperatively the colon is essentially normal by barium-enema examination. In 3 patients we have demonstrated normal colonic peristalsis postoperatively by balloon studies.

TREATMENT OF TYPHOID FEVER WITH CHLOROMYCETIN*

Results in Four Cases and in a Chronic Carrier

HARVEY S COLLINS, MD,† AND MAXWELL FINLAND, MD‡

BOSTON

CHLOROMYCETIN (Chloramphenicol) is a new antibiotic that, like aureomycin, has been of particular interest because it is effective when given by mouth and because its range of antimicrobial action includes not only many common pathogenic bacteria but also the rickettsias and the viruses of the psittacosis-lymphogranuloma-venereum group^{1,2} Of added interest is the fact that chloromycetin has been synthesized³ and that the fermentation and synthetic products have been shown to have the same activity⁴

In a preliminary report, Woodward and his co-workers⁵ found that chloromycetin exerted a specific therapeutic effect in 10 patients with typhoid fever whom they treated in Malaya In another group of cases of this disease, most of them treated in Mexico,

McDermott, Knight and Ruiz-Sanchez⁶ observed that the administration of chloromycetin was uniformly followed by prompt recovery, which, in most cases, was dramatic These observations were somewhat in contrast to experiences reported with aureomycin administration in typhoid fever, the results of which have been irregular and, on the whole, rather unimpressive⁶⁻⁹ When a supply of chloromycetin was made available,⁸ a study of its effects in typhoid fever was undertaken, and the findings in the first 4 patients and in a typhoid carrier are reported below

MATERIALS AND METHODS

The first 3 patients were treated at the Massachusetts General Hospital, and we are deeply indebted to Dr J H Means and to many other members of his visiting and resident staffs for their interest and co-operation and for the privilege of studying and reporting these cases The fourth patient was

treated on one of the medical wards of the Boston City Hospital, and the typhoid carrier was studied at the South Department of that hospital through the courtesy of Dr Edwin H. Place.

Specimens of blood, stools and urine were obtained before treatment and at intervals after treatment as indicated and feasible. The isolation and identification of the organisms from the first 3 patients were carried out in the laboratory of Dr L. Dienes, and those in the other 2 patients were done by Marion E. Lamb and A. Kathleen Daly. The sensitivity of the strains was tested by a serial dilution method on the surface of agar plates, a prepara-

improvement corresponded to the fall in temperature and convalescence was uneventful. The blood culture taken on the day chloromycetin was started was positive, but all other blood and stool cultures were negative for *Salmonella typhosa*. There were no untoward effects from the chloromycetin.

CASE 2 M. M., a 38-year-old Italian woman, was admitted to the hospital on April 27, 1949. For the previous 10 days she had been having frontal headache and fever with profuse sweating, and for 5 days she had general malaise, chilli sensations, nausea, vomiting and constipation. During the last 3 days she also complained of constant boring pain in both flanks, with radiation toward the right lower quadrant, and, in addition, she developed a dry cough with substernal soreness. On the day before entry she had a shaking chill. Her physician gave her 2 injections of 300,000 units of crystalline procaine penicillin and also oral doses of sulfadiazine, 1 gm

FIGURE 1 Course, Treatment and Laboratory Findings in Case 1

tion of crystalline chloromycetin provided by Dr E. A. Sharp being used.

CASE REPORTS

CASE 1 J. B., a 70-year-old Lithuanian, entered the hospital on April 16, 1949. For the preceding 2 weeks he had felt poorly and had been having 4 to 6 loose, nonbloody bowel movements each day. He continued to work during the first 4 days, but then, because of weakness, a slight cough, headache, anorexia and fever, he had to stay at home. His daughter, a nurse, found his temperature to range between 102 and 103°F daily during the next 10 days. She also noticed that he was apathetic and slept much more than usual. His headache and diarrhea persisted. On April 10 he had a severe shaking chill, and at that time some "red spots" were noted on his back. The family physician obtained blood and stool specimens for cultures, and when these were reported positive for typhoid bacilli he sent the patient to the hospital.

On admission the patient appeared apathetic, and the only significant findings on physical examination were a few rose spots on the abdomen and an enlarged liver. The temperature was 102.5°F, the pulse 90, and the respirations 25. The course, therapy and relevant laboratory findings are shown in Figure 1. Chloromycetin was begun on April 17, with doses of 0.5 gm by mouth every 4 hours for 6 doses and thereafter every 6 hours. A total of 25 gm was given over a period of about 12 days. The patient began to look and feel better after 3 days, and then the temperature fell gradually over the next 5 days and remained essentially normal thereafter. The pulse rate dropped from 90 to 70 during this time. The rose spots also faded over the course of the first week. General

every 4 hours, but when, after 2 days of this therapy, she failed to improve, he sent her to the hospital.

At the time of admission she was acutely ill. The positive findings on physical examination included a few small red lesions (petechiae) in the left palpebral conjunctiva and on the soft palate, marked abdominal distention without any localized tenderness and a palpable spleen.

The temperature was 105.2°F, the pulse 120, and the respirations 30. The blood pressure was 125/70.

The treatment, course and significant laboratory findings are shown in Figure 2. Sulfadiazine was discontinued after the patient entered the hospital, and penicillin 2 days later. On April 30, when the blood cultures taken on the previous days were reported as showing typhoid bacilli, oral administration of chloromycetin was started. She was given doses of 0.5 gm every 2 hours for 8 doses, and then for every 3 hours for 8 days and every 6 hours for 4 more days. When this therapy was stopped on May 13, she had received a total of 44 gm.

The course during the first few days was rather stormy. On May 2, she had a shaking chill and, because of the severe distention and vomiting, was suspected of having an intestinal perforation, the white-cell counts, however, remained low, and no air could be demonstrated under the diaphragm on x-ray study. Shortly thereafter, the patient's cough became worse and productive of thick mucopurulent sputum, cultures of which yielded a predominant growth of *Escherichia coli*. Roentgenograms of the lungs showed partial atelectasis of the right lower lobe, with marked elevation of the diaphragm on that side. Although the pulmonary signs persisted for 2 weeks, the patient's general condition began to improve rapidly after the first week of therapy. The temperature and pulse rate gradually reached normal during this time and remained so thereafter. Blood cultures taken during the

blood pressure was 125/75. No rose spots were seen, but the edge of the spleen was felt about 4 cm below the costal margin. The highlights of the course, therapy and laboratory findings, are shown in Figure 3.

On May 3 after the earlier blood and stool cultures had been reported as positive for *S. typhosa*, oral chloromycetin therapy was started. Doses of 1.0 gm each were given every 6 hours for 8 days and 0.5 gm every 6 hours for 5 more days. A total of 45 gm had been given when this therapy was stopped on May 16. On the 3rd day of this treatment the patient appeared more alert, she felt much better generally, and the stools became less frequent and less watery. The temperature dropped sharply on that day and then gradually until it became and stayed normal 3 days later. There was some fresh blood and an occasional clot in some of the stools passed during the first day, presumably from bleeding hemorrhoids. Culture of the stool obtained on the day after chloromycetin was started was positive, but all other blood, stool and urine cultures made during this course of therapy were negative for *S. typhosa*.

Convalescence appeared to be progressing uneventfully, and plans were completed for transfer of the patient to a

brisk hemorrhages from old hemorrhoids and a fistula in ano. These were repaired surgically before the patient left the hospital. Cultures of blood taken during the first 3 days and of stools taken during the first 2 days of this course of chloromycetin were positive, but all subsequent cultures, including that of some bile obtained by duodenal tube 2 days after the course was ended, were negative for *S. typhosa*.

CASE 4 H S, a 51-year-old Russian resident of Peabody, Massachusetts, was sent to the hospital on May 21, 1949. Her illness had begun on April 30 with weakness, chilliness and fever. During the 1st week she had chills, profuse sweats and mild delirium each night. She also experienced pain in the left calf and swelling of the lower leg, which made her stay off of her feet much of the time. During the 2nd week she allegedly improved, and the swelling and pain in the leg subsided but she continued to have the nocturnal chills and sweats, with occasional delirium. Her bowel movements became watery but did not increase in frequency. There were periods during each day when she became pale and faint, and she felt unsteady most of the day although she continued to do some of her housework. On May 6 a physician found the

FIGURE 4. Hospital Course in Case 4.

This patient received another course of chloromycetin for a week for thrombophlebitis shortly after discharge from the hospital. Culture of a stool obtained at the end of this course was positive for *S. typhosa*.

nursing home to recuperate when, on May 23, she again had a low-grade fever and headache. On the following day the temperature rose to 104°F, and a search for possible causes of this fever disclosed pyuria and bacilluria, a culture of the urine yielding *Esch. coli*. She was then placed on small doses of a sulfonamide. However, it was not until May 25, when cultures of blood and stools taken on the previous days were reported as positive for *S. typhosa*, that it was realized that she was suffering a relapse of the typhoid fever. The temperature by then had risen to 106°F, and the pulse to 120. The spleen which had already receded, was again palpable, headache and severe diarrhea recurred, and the patient again became drowsy and apathetic.

A second course of chloromycetin was then started, this time with 1 gm every 4 hours for about 2 weeks and every 6 hours for an additional week. This course of treatment ended on June 12, after 96.5 gm had been given. There was a sharp drop in temperature 48 hours after the treatment was resumed. During the following 4 days the temperature rose only to 100 or 101°F each day, the patient showed distinct and progressive improvement. There was marked nausea and vomiting during the first 2 days and persistent nausea throughout most of this course of treatment. During the next 2 weeks the patient was noted to have definite glossitis and cheilitis suggesting vitamin B deficiency. She also had some

temperature to be 103°F and prescribed penicillin by mouth, which she took without relief. The symptoms continued unchanged until she was sent to the hospital.

On admission, the patient appeared alert, co-operative and rather hyperactive. Her skin was clear, warm and dry. There were a few fine crepitant rales at the lung bases posteriorly. The abdomen was distended with gas, peristalsis was active, the liver edge was felt about 2 fingerbreadths below the right costal margin, and the spleen was not felt although to percussion it reached the left costal margin. There were large varicose veins of both legs but no evidence of inflammation, and there was no edema. The temperature was 105°F, the pulse 84, and the respirations 20. The blood pressure was 100/60. The patient was a diagnostic problem until the results of the blood and stool cultures taken on the day after admission were reported as positive for *S. typhosa*. The course, therapy and relevant laboratory findings are shown in Figure 4.

Chloromycetin was started on May 24, and doses of 1 gm every 4 hours were given until June 8. Therapy was stopped for 3 days in order to obtain cultures of bile and then resumed in doses of 1 gm every 6 hours until it was discontinued on June 19, after a total of 116 gm had been given. The temperature dropped to normal on the third day after the chloro-

mycetin was first begun and remained so. The patient continued to look, feel and eat fairly well until after the chloromycetin was started, when she began to complain of dizziness, a "heavy feeling in the head," sour taste in the mouth, "heartburn" and a complete lack of desire for food. She also became constipated. Most of these symptoms continued until the antibiotic was discontinued for the first time, and she vomited only on 1 day during this period. During the time when she was not taking chloromycetin, her dizziness and heartburn stopped and her appetite improved, but these symptoms and sour taste returned after she had been on the lower dosage for a week.

The blood and stool cultures taken on the day treatment was started were again positive for *S. typhosa*, but 2 subsequent blood cultures taken during the febrile period were negative. Cultures of the stools, however, continued to show *S. typhosa* throughout the entire period of chloromycetin therapy. Several stools obtained during the next 2 weeks were negative for typhoid bacilli, as were 2 specimens of duodenal content. The latter results, however, were vitiated by the fact that there was an admixture of acid gastric content.

Convalescence appeared to be uneventful when the patient was discharged home on July 1. Four days later thrombophlebitis of the left external saphenous vein, with fever and marked edema of the leg, occurred. She was admitted to another hospital, where another course of chloromycetin was given—about 2 gm. a day for 7 days. The temperature dropped rapidly from 103°F to normal, and the tenderness and swelling subsided slowly. A stool specimen sent to the State Bacteriological Laboratory after the end of this course of chloromycetin was reported as positive for typhoid bacilli and several additional cultures of stools obtained during the next 2 months were also positive for *S. typhosa*.

CASE 5 M. E. was the 73-year-old chronic typhoid carrier previously reported.⁷ Two courses of aureomycin, one during April and May 1948, and the other in July and August of that year, the latter course given after a cholecystectomy, failed to clear the patient's stools of typhoid bacilli. She was given a course of 33.5 gm. of chloromycetin by mouth, 0.5 gm. every 6 hours from March 20 to April 8, 1949. She had slight diarrhea throughout this period, but no other untoward effects. During the 6 months immediately preceding the course of chloromycetin, 25 of the 31 stools that were cultured were positive for *S. typhosa*. Between March 22 and April 18 a total of 10 stools were cultured, and all were negative for typhoid bacilli. However, 3 of 4 stools that were cultured during the following week again were positive.

The effects of chloromycetin in each of these 5 cases may be summarized briefly.

In Case 1 treatment was undertaken early in the third week of the disease with doses of 2 gm. a day. Defervescence occurred by lysis between the third and ninth days of therapy, with steady symptomatic improvement over this period. Typhoid bacilli could no longer be obtained by culture from the blood or feces after the first day of therapy, and convalescence was uneventful. There were no untoward effects from the chloromycetin in this case.

In Case 2 treatment with daily doses of 4 gm. of chloromycetin was started at the end of the second week of illness. The patient continued to be acutely ill for about a week, and the temperature dropped progressively between the fifth and eighth days of treatment. Typhoid bacilemia was demonstrated during the first two days of this therapy, but cultures of blood, urine and stools obtained after that time were all negative for *S. typhosa*, with the possible exception of the blood culture made on the second day after the treatment was stopped. Rather severe and persistent vomiting occurred during the first week of chloromycetin administration, and

may have been responsible for the delayed response in this patient.

In Case 3 there was a full-blown clinical and bacteriologic relapse after an apparently good response to an initial course of chloromycetin that was begun in the middle of the second week of the disease and consisted of 43 gm. given over a period of thirteen days. Improvement again followed quite promptly after a second and more intensive course of chloromycetin was started. There were no untoward effects from the first course, but the patient was nauseated throughout most of the second course and vomited several times soon after the larger dosage was started. This patient also experienced glossitis and cheilitis that may have been attributable, in part, to the antibiotic.

In Case 4 treatment with 6 gm. of chloromycetin daily was started during the middle of the fourth week of the disease, and the patient maintained for two full weeks on that dosage and for an additional week on 4 gm. a day. She became and remained afebrile after the third day of this therapy, but she continued to shed typhoid bacilli in her stools throughout the period of treatment and the organisms were recovered again more than three months later. The effect of therapy on the symptomatology was difficult to evaluate in this case. Distressing gastric symptoms accompanied the larger doses of the antibiotic, but were less marked and somewhat delayed during the second course when smaller doses were given.

In the chronic carrier, typhoid bacilli could not be isolated from the stools during the two weeks of chloromycetin therapy and for a brief period thereafter. The organisms then reappeared in the stools and could be recovered quite regularly. This patient experienced mild diarrhea but no upper gastrointestinal symptoms while taking the antibiotic.

SENSITIVITY OF THE STRAINS

The strains of *S. typhosa* that were isolated from these patients and tested were found to be about equally sensitive to chloromycetin. They were all partially inhibited in concentrations of 4 microgm. per cubic centimeter, some of them were completely inhibited in the same concentration, whereas others required twice that concentration for complete inhibition. All strains isolated from different sources and at different times from the same patient showed the same sensitivity to chloromycetin. There was no tendency for the development of increased resistance during treatment.

DISCUSSION

It is quite apparent from the results obtained in this small group of patients that chloromycetin, although it may have had a beneficial effect on the course of the acute disease, did not produce the dramatic effects that were expected. The persistence of the organisms in the stools in Case 4 and in the

carrier, the clinical and bacteriologic relapse in Case 3 and the rather slow defervescence in 3 of the 4 acute cases indicate that chloromycetin, like aureomycin, still leaves much to be desired as a curative therapy for typhoid fever. Relapses with bacteremia were also noted in 2 of the 10 chloromycetin-treated patients reported from Malaya⁵ and were not uncommon after treatment with either chloromycetin or aureomycin among the cases studied by McDermott, Knight and Ruiz-Sanchez.⁶ Serious complications, an intestinal hemorrhage in 1 case and perforation in another, occurred on the fourth and the second afebrile day, respectively, in 2 additional chloromycetin-treated patients from Malaya.⁵

The possibility that strain differences account for the variations in response to treatment was considered. Phage typings* indicated that the strains from the acute cases all belonged to the same phage type (E), whereas the carrier's strain was of a different type (A). Differences in response dependent on the host or on the nature of the lesion at the time treatment was started cannot be ruled out. With respect to the latter, McDermott et al.⁶ considered that aureomycin exerted an effect on the course of the infection particularly when treatment was started during the first ten days of the disease. These effects were seldom dramatic, however, and in well established infections (third week) were frequently negligible. Chloromycetin administration, by contrast, was uniformly followed by prompt and usually dramatic recovery in their experience.⁶

Although McDermott and his colleagues found chloromycetin to be markedly superior to aureomycin as a therapeutic agent in typhoid fever, our own limited experience to date shows that, except for a lower incidence of gastric symptoms with chloromycetin, the difference between the effects of these antibiotics has not been so striking. Such differences may become more apparent, however, with further experience in a larger group of cases. Diagnosis and initiation of treatment early in the disease and possibly the use of maximal doses from the start and continued for long periods may be determining factors in the success of both these agents in some cases.

The recent studies of Seligmann and Wassermann¹⁰ on the action of chloromycetin on sal-

monella are of interest in relation to the findings in the present cases and particularly with respect to the failure to eliminate typhoid bacilli from the feces in Case 4 and in the chronic typhoid carrier. All of 23 salmonella types that these authors studied, including *S. typhosa*, were sensitive to 2 or 4 microgm. However, in experimental infections with *Salmonella typhimurium* in mice, chloromycetin failed to control the infection and exerted no influence on the intestinal flora when given orally or subcutaneously even in large doses and when treatment was started immediately after infection.

SUMMARY

The effect of chloromycetin (Chloramphenicol) on the clinical course and laboratory findings in 4 patients with typhoid fever is discussed. Clinical improvement and defervescence began on the third day after treatment had been initiated in each case and was complete after about a week of therapy. One of the patients had a relapse with bacteremia after the temperature had been normal for two weeks. A second patient continued to shed typhoid bacilli in the stools throughout three weeks of chloromycetin administration and again during convalescence.

Chloromycetin, given in doses of 2 gm a day for two weeks, failed to cure a chronic typhoid carrier whose gall bladder had previously been removed.

USE OF DIETHYLSTILBESTROL TO PREVENT FETAL LOSS FROM COMPLICATIONS OF LATE PREGNANCY*

O WATKINS SMITH, PH D,† AND GEORGE VAN S SMITH, M D‡

BROOKLINE, MASSACHUSETTS

THE present communication deals with further progress in a clinical evaluation of our concept concerning the action of diethylstilbestrol in human pregnancy. Analyses of results in 632 pregnancies during which this drug was given in the manner recommended by us have been reported.¹ In 491 of these cases stilbestrol was administered for the prevention or treatment of abortion. A preliminary report was included, however, upon its use in 95 patients for the purpose of preventing complications of late pregnancy. These 95 cases are included in the present study of a total of 180 women in whom the indication for therapy was diabetes, essential hypertension, nephritis or a past obstetric history of pre-eclampsia, eclampsia, premature delivery or unexplained intrauterine death of the fetus.

The use of stilbestrol in pregnancy is based upon experimental evidence for its progesterone-stimulating effect in rats² and in pregnant women.³⁻⁵ The indications for such therapy and the dosage schedule recommended have been presented.¹ We were particularly interested in its possible value for the prevention of complications of late pregnancy, since a premature deficiency of the placenta in the secretion of estrogen and progesterone before and during late-pregnancy toxemia, premature delivery and intrauterine death had been shown by our own studies and confirmed by others.⁶ We have emphasized the fact that whatever the primary etiologies of these complications may be, a premature deficiency of estrogen and progesterone sooner or later is involved and becomes an intermediate contributing factor. Moreover, we have laid emphasis upon the reciprocal relation between vascular supply to the uterus and hormonal support, adequate vascularity being as essential for the normal production of the placental steroid hormones as adequate hormonal support for the increased vascular demands of the pregnant uterus. By supplying an extra stimulus for the secretion of estrogen and progesterone, we are attempting to combat only one of the contributory factors of the final syndrome. If a more normal secretion of estrogen and progesterone is accomplished, however, the vascular deficiency should be minimized, since the combined

action of these two steroid hormones is characteristically one of vascular and myometrial growth. Experimental and clinical experience indicates that neither one of them alone could accomplish the degree of uterine growth and vascularity required in late pregnancy. Improved clinical results in themselves, therefore, would provide added support for the stimulative effect of stilbestrol upon the placental secretion of both the sex steroids.

From these considerations it is apparent that stilbestrol administration could not be expected completely to prevent late-pregnancy complications. By combating one of the contributory factors in vascular deficiency, however, we might well postpone, if not entirely avert, the onset of the final clinical abnormality. This in itself would result in less damage to the mother and a greater chance for fetal survival.

SOURCE OF CLINICAL MATERIAL

We are indebted to 58 obstetricians for the records of 104 of the 180 pregnancies to be reported, our method of acquiring this information being the same as that previously described.¹ The other 76 women were patients referred to us at the Boston Lying-in Hospital, where they received their prenatal and obstetric care. All of them took stilbestrol by mouth according to the dosage schedule used in our first study.¹ In no case was the therapy begun later than the nineteenth week and in the majority it was given from the start of the seventh to twelfth weeks. *We do not recommend diethylstilbestrol except as a preventive measure for late-pregnancy toxemia.* This statement is based on both theoretical grounds and actual experience.^{1, 4}

CLINICAL RESULTS

Table 1 presents the over-all data on the 180 women to whom stilbestrol was given to prevent late-pregnancy complications. Only 10 were primigravidae; 4 of 14 diabetic patients and 6 of 50 who had hypertension, either essential or secondary to nephritis. The other 170 patients had had a total of 380 previous pregnancies, of which only 28 (7.4 per cent) had progressed normally to term with no complications involving either the mother or child. Fifteen per cent had spontaneously aborted. The other 78 per cent of previous pregnancies had been complicated by spontaneous premature delivery, unexplained stillbirth or toxemia. The total

§E. R. Squibb and Sons supplied the 25.0-mg. tablets of stilbestrol used in this study.

fetal salvage from these 380 pregnancies had been 116 living babies or 30 per cent

Although the over-all outcome of the present pregnancies on stilbestrol is obviously a great improvement over the past obstetric histories a fair evaluation of the effect of stilbestrol administration cannot be made without a more detailed analysis, as pointed out below

In evaluating the results of stilbestrol therapy for threatened and chronic abortion¹ we had reliable figures on the spontaneous cure rates of these conditions as a basis for statistical analysis of our data. No such generally accepted figures are available, so far as we know, as a basis for evaluating any prophylactic therapy against

essential or secondary to renal disease. These were women either known to have essential hypertension or nephritis or found to have a blood pressure of 140 systolic, 90 diastolic or above in at least two readings prior to the twenty-second week. The ages ranged from twenty to forty-four years, and 33 of them (66 per cent) were over thirty years old. Seven had chronic nephritis. Forty-four of these women (88 per cent) were multigravidas with poor obstetric histories. There were no twins in past deliveries, but 3 of the 50 women had twins while on stilbestrol making a total of 53 possible infants.

By stimulation of maximum secretion of the placental steroid hormones through stilbestrol administration, it was postulated that the uterine vascular deficiency associated with hypertension might be at least partially counteracted and obstetric complications thereby minimized. The results of stilbestrol therapy are presented in Table 2 and may be evaluated by comparison with the past 105 pregnancies of these same patients when no stilbestrol was administered. Inasmuch as hypertension is a progressive disease, this means of evaluation appears to be valid.

Fetal loss was reduced from 53 to 15 per cent. Cosgrove and Chesley² have placed the fetal loss in all pregnant women with essential hypertension, regardless of severity, at 38 per cent. At the Boston Lying-in Hospital between 1932 and 1948 the total fetal loss in 138 hypertensive patients was 64 per cent with a 40 per cent mortality in the 84 babies

complications of late pregnancy. In a planned study that is being separately reported,³ the course and outcome of the pregnancies of 387 primigravidas on our dosage schedule of stilbestrol are compared with those of 555 synchronous control primigravidas who received the same prenatal and obstetric care. In this study statistical analysis was possible and showed a highly significant difference between treated and control cases in the matter of the incidence and severity of toxemia and of fetal loss from late-pregnancy complications. From these results it seems safe to assume that the use of diethylstilbestrol should be effective as a preventive measure in patients in whom complications of late pregnancy may be anticipated. In evaluation of the present study on just such cases however certain difficulties are encountered. Lacking reliable information on spontaneous cure rates and considering the heterogeneous nature of the clinical material we can only break down the data in various ways that seem to warrant a comparison of the outcome on stilbestrol with the past obstetric histories of the same patients.

Essential Hypertension and Nephritis

Of the 180 patients observed, 50 were given stilbestrol because of pre-existing hypertension either

‡At less than 37 weeks.

that reached viability. * Forty-nine infants of the stilbestrol-treated hypertensive patients attained viability. Only 4 of these, 8.1 per cent, were lost, as against a 40 per cent mortality among their 81 previous babies that had reached viability. It seems clear therefore, that the fetal loss in these 50 stilbestrol-treated patients was considerably less than might have been expected. The factors involved (Table 2) are discussed below.

*We are indebted to Dr. William J. Mulligan for collecting this information from the record room of the Boston Lying-in Hospital.

The incidence of spontaneous delivery prior to the thirty-seventh week was not reduced, probably because many patients who would have aborted without stilbestrol carried their pregnancies beyond the twenty-second week but not to term. Fetal mortality from prematurity, however, was less than half that of the previous pregnancies. As shown below, there is good indication that the premature baby of a stilbestrol-treated mother is unusually mature for its gestational age.

There were 6 unexplained stillbirths in the past obstetric histories of these patients, an incidence of 5.7 per cent. No stillbirths occurred on stilbestrol.

Any rise in blood pressure during the last two months above the level noted prior to twenty-two

third, that of an infant delivered by cesarean section at thirty-one weeks because of an increase in toxic signs in a patient who had had kidney damage as well as severe hypertension (blood pressure of 210 systolic, 110 diastolic) before pregnancy began. (This was the only fetal death in this series of 50 patients that was associated with superimposed toxemia.) The past obstetric histories of all these patients, however, gave good indication that the disease was sufficiently severe to endanger pregnancy. Although the use of stilbestrol should not supplant clinical judgment in the management of hypertension complicated by pregnancy, it appears, from the results presented, that its prophylactic administration to patients in whom early interruption is not indicated reduces the incidence of superimposed toxemia (thereby minimizing further damage to the vascular system) and greatly increases the chances of obtaining a living child.

*At least 2 of these occurred after 22 weeks. The total number of previous pregnancies was 201.

†At less than 22 weeks.

‡At less than 37 weeks.

weeks, any albuminuria in patients with no pre-existing renal disease or increased albuminuria in those with nephritis constituted a diagnosis of superimposed toxemia. There was a significant reduction in the incidence of this complication, from 52 to 28 per cent, and an even more striking decrease in fetal mortality—there was only 1 fetal death associated with superimposed toxemia in the pregnancies when stilbestrol was being taken, an incidence of 7 per cent, whereas 12, or 22 per cent, of their previous 55 toxic pregnancies had resulted in loss of the infant.

Finally, the past history of these patients had only 13 uncomplicated pregnancies, an incidence of 12 per cent, whereas nearly half the same patients, when given stilbestrol from early in pregnancy, delivered at term with no obstetric complications whatsoever.

The gratifying results in these 50 patients should be moderated by the explanation that only 12 of them had diastolic pressures above 100 prior to the twenty-second week, these being the only ones in whom the severity of the pre-existing disease might have made early interruption advisable. In these 12 cases there were 3 fetal deaths, 1 due to spontaneous abortion at twenty weeks, 1 to spontaneous premature delivery at twenty-six weeks and the

Sequences of Late-Pregnancy Complications

Of the 180 women to whom stilbestrol was given for the prevention of complications of late pregnancy, 49 had had 3 or more previous consecutive pregnancies that had been complicated by some abnormality associated with a deficiency of the placental steroid hormones. There were a number of abortions in the over-all past histories, but the last 3 pregnancies of each patient had included at least 2 in which complications developed after the twenty-second week. Forty-four of these women (90 per cent) had never had a full-term, uncomplicated pregnancy, although none of them had had less than 3 previous gestations and the average number was 4.3. Considering the repetitive nature of late-pregnancy complications in this group of women, it seems valid to base evaluation of stilbestrol treatment upon a comparison with their past obstetric histories. Such a comparison is presented in Table 3.

Although spontaneous abortion was markedly lowered, there was no significant reduction in the incidence of spontaneous premature delivery, possibly because patients who would have aborted without stilbestrol progressed beyond the twenty-second week, but were still unable to carry on to term. Fetal loss from prematurity, however, was reduced from 72 to 18 per cent. The factors that appear to be operative in the reduction of fetal mortality from prematurity when stilbestrol is given are discussed below.

Of the 145 fetal deaths in the previous pregnancies of these patients, 26 were accountable to unexplained stillbirths. The incidence of this abnormality was considerably reduced, from 13 per cent in the previous pregnancies to 4 per cent when stilbestrol was administered.

Twenty-three of the 49 women had had pre-eclampsia or eclampsia (2 cases) in previous pregnancies, with a total of 50 late-pregnancy toxemias

in the past obstetric histories. Fourteen women had had this complication in at least 2 consecutive pregnancies prior to the one in which stilbestrol was given. There was no eclampsia on stilbestrol. The incidence of toxemia was reduced from 24 per cent in the past obstetric histories to 8 per cent on stilbestrol, and the fetal mortality associated with this disease from 44 to 25 per cent.

A small number of the previous pregnancies of these 49 women (6 per cent) had been complicated by bleeding during the last trimester. Only one (2 per cent) had this abnormality on stilbestrol.

Finally, on stilbestrol, 30 of these women (61 per cent) went through pregnancy to term with no complications whatsoever, whereas only 7 per cent of the previous 201 pregnancies had been uncomplicated. Forty-two of them (85 per cent) gave birth to children that lived, as against only a 27 per cent fetal salvage in the past obstetric histories. Of these 49 women, all of whom had had 3 or more previous pregnancies, 17 had no living children

was 4, or 28 per cent, which is high but is a distinct improvement.

Among our records on 804 "obstetric problem cases," including the 66 referred to above, in which stilbestrol was given according to our dosage schedule for complications of early or late pregnancy, there was a total of 65 cases in which late-pregnancy toxemia was diagnosed. The 14 cases discussed above were the only ones in patients who had a previous history of toxemia, and the only fetal deaths were the 4 that occurred in these patients—an over-all fetal mortality from toxemia of 6.2 per cent. This is an impressive figure only when one considers that in all these women obstetric difficulties were anticipated and that 43 per cent of the 94 toxic pregnancies of their past obstetric histories had resulted in death of the fetus.

Spontaneous Premature Delivery

Prematurity accounts for more fetal deaths than any other single obstetric abnormality except abor-

*The total of fetal deaths was 133 among 172 previous pregnancies (77%) and 15 among 76 pregnancies on stilbestrol. There were 23 abortions in the past obstetric histories and none on stilbestrol.

prior to the administration of stilbestrol. Twelve of these, or 71 per cent, now have living and well babies.

Pre-eclampsia and Eclampsia

Of the 180 women being reported, 66 had had a total of 94 toxic pregnancies prior to the one in which stilbestrol was administered. Eight of these had had eclampsia. The results of a very extensive study of toxemia by Mastboom, of Amsterdam,⁹ revealed 30 per cent and 56 per cent recurrence of toxemia after a previous eclampsia and pre-eclampsia, respectively. Accordingly, 35 of these 66 women, or 53 per cent, would have been expected to have toxemia in the pregnancy in which stilbestrol was given. Actually, only 14, or 21 per cent, had this complication—a highly significant reduction if Mastboom's figures are acceptable in this country.

In the 94 previous toxic pregnancies there were 41 fetal deaths—a mortality of 43 per cent. In the 14 toxic pregnancies that the same patients had despite stilbestrol, the fetal loss from toxemia

Of the 180 women treated for the prevention of late-pregnancy complications, 76 had a history of spontaneous premature delivery. In this category we are omitting stillbirths and premature delivery associated with toxemia. One hundred and forty-three (83 per cent) of the previous 172 fetuses had been born alive spontaneously between the twenty-second and thirty-seventh weeks, and 108 of these (76 per cent) had died of prematurity.

In Table 4 these patients are grouped according to the number of premature deliveries that they had had prior to the pregnancy in which stilbestrol was prophylactically administered. In each group there was a considerable decrease in the incidence of prematurity, but, as has been pointed out elsewhere,^{1, 7} about half the women who tend to deliver early cannot be carried to term on stilbestrol. This suggests that in half these cases the primary etiology lies in some abnormality that cannot be entirely counteracted by stilbestrol administration. We have repeatedly emphasized the reciprocal relation that exists between the vascular supply to the uterus and the secretion of the placental steroid

hormones, estrogen and progesterone Adequate vascularity depends upon adequate hormonal support, but any condition that adversely affects the blood supply to the uterus has a detrimental effect upon the production and metabolism of the placental steroid hormones An inherent hypertonicity of the uterus, for example, could readily interfere with a completely normal secretion of estrogen and progesterone even when the extra stimulation for such secretion, which we believe to be supplied by stilbestrol administration, is provided It seems probable that the tendency to deliver early can often be ascribed to some such mechanical interference with blood supply to the growing products of conception

Despite the fact that half these 76 women delivered early even when taking stilbestrol, 80 per cent of them gave birth to living and well babies, whereas less than a quarter of their previous 172 pregnancies had terminated in living children This marked improvement in fetal salvage may be accounted to the fact that along with the reduction in the incidence of premature delivery there was a considerable reduction in fetal loss from prematurity (Table 4) This is apparent in all groups regardless of the number of previous premature deliveries As clinical results have accumulated, the impression has grown that the premature babies of stilbestrol-treated mothers are exceptionally large and "rugged"

TABLE 5 Incidence of Prematurity in 1191 Patients on Stilbestrol

for their gestational ages This impression is borne out by the following analysis of our data

Premature Babies of Stilbestrol-Treated Mothers

The definition of prematurity accepted by the American Academy of Pediatrics¹⁰ is "any infant born alive who weighs 2500 gm (5 pounds, 8 ounces) or less" In presenting our data we have purposely adhered to gestational age rather than weight, partly because the past obstetric histories often gave no information concerning weights of infants and therefore no means of comparison, and partly because so many of the prematurely born infants of stilbestrol-treated mothers weighed more than 5½ pounds To determine just what effect stilbestrol had upon babies born early, we have analyzed our data concerning all those delivered fourteen days or more before term by 1191 women (to

March 1, 1949) who took stilbestrol during pregnancy according to our dosage schedules Three hundred and eighty-seven of these were primigravidas at the Boston Lying-in Hospital, a part of a twenty-one-month study in which alternate normal primigravidas were treated so that results could be compared with a group of synchronous controls receiving the same prenatal care⁷ The other 804 patients were treated either for threatened abortion or prophylactically for the prevention of early or late obstetric complications that might have

FIGURE 1 Birth Weights of Infants Born More Than Fourteen Days before Estimated Date of Confinement (Omitting Twins and Diabetic Patients)

been anticipated in view of their medical or past obstetric histories For the sake of brevity these 804 patients are termed "obstetric problem cases" All live-born infants delivered two weeks or more before term are included, whether or not the pregnancy was normal or the delivery spontaneous

In Table 5 the incidence of prematurity is presented on the basis both of dates and of birth weights In the normal primigravidas the incidence of prematurity was only 2.8 per cent according to birth weight, whereas 12 per cent were born early In the obstetric problem cases, as might be expected, the definition of prematurity had a less marked influence upon the percentage incidence, since more of these women delivered very early and had small infants That most of their babies were large for their gestational ages, however, is

shown in Fig 1 and 2, in which scattergrams for the length and weight are presented in relation to curves based on averages. The upper curve in both these charts was determined by Ylppö in 1919 and the lower by Scammon and Calkins between 1922 and 1925.¹¹ Of the 127 babies born fourteen days or more before term, 109 (86 per cent) were above average in weight. Unfortunately, accurate data on the crown-heel length were available in only 41 cases, but 37 of these (90 per cent) fell above the average curve. In the series of 387 primigravidas at the Boston Lying-in Hospital (a study being reported elsewhere⁷), over 90 per cent of the

FIGURE 2 Available Information on Crown-Heel Length of Infants Born More Than Fourteen Days before Estimated Date of Confinement

41 premature infants of treated patients fell above the average curves for both weight and length, whereas in the synchronous control group of 63 premature babies of 555 primigravidas who received no stilbestrol the figure was 60 per cent. If these average curves are applicable to the present-day population, one would expect a scattergram of controls to fall 50 per cent above and 50 per cent below the lines. Sixty per cent above the average in a scattergram of 63 control cases is not a significant deviation. We may assume, therefore, that the upper curves for weight and length of Ylppö (1919) still provide a sound basis for evaluation.

This evidence for the greater size and maturity of premature babies delivered to stilbestrol-treated mothers seemed sufficient explanation for their greater chances for survival. It was of interest to discover, however, how our mortality rate in infants weighing 2500 gm. or less would compare with vital statistics on premature infants as a whole.

TABLE 6 Mortality in Premature Infants*

Stilbestrol-treated mothers (1191 cases) — Smith and Smith dosage schedule	1943-48	126	6.3

*Weight of 2500 gm. or less

Among 1191 deliveries of stilbestrol-treated mothers there were 126 babies weighing 2500 gm (5 pounds, 8 ounces) or less. Eight of these, or 6.3 per cent, died. In Table 6 this figure is compared with similar statistics from a number of hospitals* and is shown to be very significantly lower than that of the Boston Lying-in Hospital, the lowest of the group. This could be due, of course, to fewer very small babies born to the mothers who had taken stilbestrol. That this is not the explanation, however, is shown in Table 7, in which the total fetal mortality is broken down into groups according to birth weight.

TABLE 7 Distribution of Birth and Mortality Rates in Premature Infants*

BIRTH WEIGHT	BOSTON LYING-IN HOSPITAL (1944-1948)	STILBESTROL-TREATED MOTHERS (1943-1948)
	TOTAL PREMATURE INFANTS	TOTAL PREMATURE INFANTS

Averages		6.3

*Weight of 2500 gm. or less

and the results compared with similar figures from the Boston Lying-in Hospital for the years 1944-1948*. In each weight group the fetal mortality is lower than that at the Boston Lying-in Hospital. The indication is, therefore, that regardless of size, the babies of stilbestrol-treated patients are more likely to survive.

In a 1948 publication by Koch, Weymuller and James,¹² the following statement was made: "Mortality from premature birth can obviously be re-

*We are indebted to Dr. Stewart H. Clifford, associate in pediatrics, Harvard Medical School, for the vital statistics on premature infants used and for advice in analyzing our data.

duced in but two ways, either by an actual over-all reduction in the incidence of premature birth or by improvement in methods of care of the premature infant after birth." It appears from the figures presented above on the babies of stilbestrol-treated mothers that a third way of reducing fetal mortality from premature delivery should be added to this statement — namely, by improving the vascular supply to the uterus and thereby providing a better maternal environment for the fetus so that even if it is delivered prematurely it will be in better condition and actually more mature than would be expected from its gestational age. The administration of stilbestrol as a prophylactic measure appears to be one way in which this may be accomplished. Our interpretation is that even in cases in which the primary cause of premature delivery cannot be counteracted, the placental secretion of estrogen and progesterone is stimulated to its maximum capacity up to the time when non-hormonal factors gain the supremacy and bring on the vascular and hormonal deficiency associated with the onset of labor.⁶

SUMMARY

The progress and outcome of pregnancy in 180 women to whom stilbestrol was administered for the prevention of late-pregnancy complications are reported. In the evaluation of results we have relied largely upon grouping the cases in various manners so that the outcome on stilbestrol could be compared with the past obstetric histories of the same patients. All but 10 of them were multigravidas with a total of 380 previous pregnancies, only 7.5 per cent of which had been normal. Fifteen per cent of their previous pregnancies had terminated in spontaneous abortion. The other 78 per cent had been complicated by spontaneous premature delivery, unexplained stillbirth or toxemia.

Fifty women had pre-existing hypertension, either essential or secondary to renal disease. In the past obstetric histories of 105 pregnancies (no twins), there had been a 23 per cent fetal loss from spontaneous abortion and a further 30 per cent fetal loss from late-pregnancy accidents. On stilbestrol there were 3 twin pregnancies making a total of 53 fetuses. Four of these (7.5 per cent) were aborted, and another 4 (7.5 per cent) lost after the period of viability. The factors operative in the reduction in fetal mortality during later pregnancy were a lowered incidence of superimposed toxemia and of unexplained stillbirth and a decrease in fetal mortality in prematurely delivered infants.

Forty-nine patients had had a sequence of 3 or more consecutive pregnancies prior to stilbestrol in which complications associated with progesterone

deficiency had occurred. In at least 2 of the 3 the abnormalities had developed after the period of viability. Only 3 per cent of the previous 201 pregnancies had been normal, and only 27 per cent of the offspring had survived. On stilbestrol 61 per cent of patients had no obstetric complications, and 85 per cent gave birth to living children.

Sixty-six women had had pre-eclampsia or eclampsia in 94 of their previous pregnancies, with 41 fetal deaths, a mortality rate of 43 per cent from this disease. According to Mastboom, 35 of these 66 women would have been expected to have toxemia in the pregnancy in which stilbestrol was given. Actually, only 14 of them had this complication with a 28 per cent fetal mortality. Among our records on 804 "obstetric problem cases" in which stilbestrol was administered for one reason or another there were 65 toxic pregnancies including these 14. The over-all fetal mortality from toxemia on stilbestrol was 6.2 per cent, as against 43 per cent in the past obstetric histories of the same patients.

Seventy-six women had had spontaneous premature delivery in 83 per cent of their pregnancies prior to the one in which stilbestrol was given. Forty-nine per cent again delivered prematurely despite stilbestrol administration. The fetal loss, however, was reduced from 77 per cent in the past obstetric histories to 20 per cent on stilbestrol.

Analysis of our over-all data on the prematurely delivered infants of stilbestrol-treated mothers indicates that these babies are exceptionally heavy and long for their gestational ages and that, regardless of size, more of them survived than would have been expected from recent statistics on the mortality rates of premature infants.

PITFALLS OF CHEMOTHERAPY AND ANTIBIOTICS IN SURGERY*

ALLEN G RICE, M D †

SPRINGFIELD, MASSACHUSETTS

ACCORDING to Webster's dictionary, a pitfall is defined as an error into which the unwary may unsuspectingly drop. By the same authority an error may be one of omission or commission. It may be stated that the pitfalls of chemotherapy and antibiotics are of two kinds: those that are liable to waylay all these agents, and those that are selective in their iniquity. Perhaps the worst error made with these remedies is to endow them as panaceas. True, they cure a few diseases all the time and others some of the time, but never all diseases all the time. The abandon with which they are prescribed, notably penicillin, for nearly every ailment under the sun, from the rectum to the ear, is astounding. So great is unwarranted faith in their infallibility that they are too often prescribed without an accurate diagnosis and detection of the causative organism.

The common error of indiscriminate use of these agents promotes three untoward and likewise common sequelae. The first is that all these chemical and biologic remedies have to some degree the insidious ability to stimulate in the organisms against which they are pitted a resistance that defeats the aim in view. There is already evidence, for example, that a new strain of a troublesome diplococcus has built up such resistance to formerly effective therapy that the drug is on its way to impotence. If an almost specific remedy can be so frustrated when wisely used, how serious it is to foster the acquisition of such resistance unnecessarily! Secondly, these remedies can sensitize persons who happen to be susceptible. This sensitization may be provoked by a small dose given unnecessarily, and may not be manifested until real need for the drug arises and then, because of the heedlessly acquired sensitivity, it cannot be tolerated. Thirdly, all these medications have untoward, and sometimes perilous, effects that can be forestalled only by careful and frequent laboratory checks too often disdained.

Another common pitfall, but of a different order, is the unwarranted assumption that the drugs can wholly replace surgery in the treatment of suppurative ailments. Admittedly, they are adjuncts and valuable ones in the handling of surgical conditions. Their proper and timely use not only often lessens the extent of necessary operation but also saves lives that surgery alone might lose. They are never, however, reliable substitutes for indicated surgery. In all fairness it should be stressed that it is not so much the drugs themselves that are beset with pitfalls as their promiscuous and ill advised use.

*Presented at the annual meeting of the Massachusetts Medical Society, Worcester, May 25, 1949.

†Consulting surgeon, Springfield Hospital.

More grievous perhaps are the special pitfalls peculiar to individual antibiotics and chemotherapeutic agents. Chief of the latter group are the sulfonamides. The early preparations of sulfur compounds quite often induced alarming, sometimes even fatal, untoward effects because of their high toxicity. Subsequent preparations, however, have been generally rid of toxic evils and can be prescribed with comparative safety but, especially when they are given for prolonged periods, it is still wise to check quite frequently for possible blood damage. At any rate the use of known toxic preparations can no longer be condoned. Sulfadiazine is perhaps the least toxic and has the real virtue of general effectiveness against many strains of bacteria. The newer compounds are held to be selective in action: sulfanilamide for streptococci, sulfathiazole for staphylococci and such rather insoluble compounds as sulfasuxidine, sulfaguanidine and sulfathalidine for intestinal flora, but too much faith cannot be placed in their selectivity.

It is now generally accepted that the sulfonamides act most effectively by way of the blood stream. They are still being locally applied, though their local action is slight and their local application is not without harm. On burned surfaces, for example, their absorption is uncertain and unpredictable, either too little and too slow to be useful or so great and so rapid as to become alarmingly toxic. Furthermore, since locally they become foreign bodies, they are known to delay healing, probably arousing excessive scar formation, and in the peritoneal cavity they are guilty of promoting adhesions.

The pitfalls that waylay the antibiotics are apt, because of their comparative safety, to be disregarded or forgotten. Penicillin, for example, is not always kindly tolerated. Soon after its administration such allergic reactions as urticaria, rhinitis and asthma may appear, and a few days later true dermatitis and serum sickness may occur. Even fatal anaphylactic shock has been reported.

Penicillin should be withheld until the identity of the infecting organism is established, otherwise, premature use of the antibiotic will cloud the etiologic picture. Once, however, the indication for penicillin is clear beyond peradventure, it is a grievous sin of omission to be stingy with it. Large and frequent doses are required. Even more essential is it not to stop the drug too soon. An effective blood level must be maintained until it is certain that all danger has passed. Only too often, patients who have been getting penicillin in the hospital are discharged without provision having been

made to continue it, and the omission allows disturbing symptoms of infection to recur

Streptomycin is not so generally effective as penicillin. Perhaps its outstanding virtue is in tuberculosis, against which penicillin is of no avail. Unfortunately, however, the tubercle bacillus acquires resistance to streptomycin in about six weeks on average doses. Now that pulmonary tuberculosis is safely and auspiciously attacked by surgical operation, chest surgeons have sounded a serious and timely warning not to give streptomycin to patients headed for thoracoplasty. Surgeons want to be able to count on streptomycin postoperatively to take care of any spread of the disease occasioned by operation. If a patient has already acquired preoperative resistance to streptomycin, he has forfeited a postoperative aid of great value.

As could be expected, sins of omission in chemotherapy and with antibiotics are few. Perhaps the most flagrant pitfall of the kind is failure to take full advantage of the added benefit gained by a combination of these agents. Peritonitis from appendicitis or perforated viscus, for example, is due to accumulative action of aerobes and anaerobes, which act synergistically to heighten each other's virulence. Unless penicillin, streptomycin and the

sulfonamides are energetically used, there is little chance of breaking up the synergism and overcoming the infection. In like manner, if happy outcomes are sought in such infections as carbuncles, septic hands and lymphangitis, there must be no retreat from a course of large, frequent and long-continued doses of antibiotics. Again, the mere fact that antibiotics taken orally are in some measure helpful does not warrant abandonment of the much more effective parenteral routes for the sake of sparing patients needle pricks.

Lest this paper leave an impression of pessimism and therapeutic nihilism, it should be stressed that if chemotherapeutic agents and antibiotics are regarded not as panaceas but as wondrously helpful surgical adjuncts, if they are prescribed wisely and opportunely and if their untowardnesses are constantly forestalled by the eternal vigilance that is the price of surgical success, the pitfalls that beset chemotherapy and antibiotics in surgery are easily avoided and the virtues of these agents made profitable. In the offing are more antibiotics. One and all must be studied, their limitations established, and their liabilities noted, lest they present new pitfalls to mire the unwary and lest avoidable errors be committed in their use.

MEDICAL PROGRESS

MEASURES USED IN THE PREVENTION AND TREATMENT OF CARDIAC ARRHYTHMIAS*

ARTHUR J. LINENTHAL, M.D.,† AND A. STONE FREEDBERG, M.D.‡

BOSTON

THE management of cardiac arrhythmias is a common and important clinical problem. Although we shall not discuss diagnosis, it must be emphasized that accurate diagnosis of the nature of an arrhythmia is of the utmost importance since therapy useful in certain arrhythmias may be ineffective or harmful in others. In addition to reassurance, sedation, avoidance of possible precipitating factors (such as alcohol, caffeine, tobacco, emotion and exertion) and the treatment of commonly associated diseases (such as acute myocardial infarction, infections and thyrotoxicosis), specific measures affecting the rate and rhythm of the heart may be indicated. A large number of drugs and other measures have been used and are continually being recommended for

both the prevention and the treatment of cardiac arrhythmias (Table 1). It is our purpose to assemble and to analyze the available information, to indicate the order in which the various measures should be tried in an individual case, to suggest ways in which the use of available agents may be improved, to point out agents that seem particularly worthy of more extensive clinical trial, and to emphasize the criteria that are necessary in evaluation of prophylactic and therapeutic efficacy.

EVALUATION OF EFFICACY AND TOXICITY

In paroxysmal tachycardia the efficacy of a drug is measured by its ability to terminate the arrhythmia, although it is generally impossible to observe the precise instant that termination occurs. There may be little question of the association of events when the desired result is observed repeatedly after immediately effective measures such as carotid-sinus pressure and intravenous injection of acetylcholine. Several hours may elapse, however, before the arrhythmia stops after more slowly act-

ing agents — for example, quinidine administered orally, — and the relation may not be so obvious

These considerations pertain also to the evaluation of drug toxicity, which is especially difficult in cardiac patients. Changes in the heart rate and rhythm, respiratory and central-nervous-system phenomena and various other manifestations, including sudden death, that may be due to drug toxicity may also occur in the natural course of many forms of heart disease

MEASURES AFFECTING THE PARASYMPATHETIC SYSTEM

Reflex stimulation of the vagus nerves to the heart and administration of parasympathomimetic

more, vagal stimulation by carotid-sinus pressure or eyeball pressure, for example, affects only the heart and peripheral vessels, whereas the parasympathomimetic drugs stimulate all cholinergic nerve endings to a varying degree. Side reactions that almost invariably accompany the use of drugs are rarely seen. Some form of reflex vagal stimulation, therefore, is indicated as the initial therapeutic procedure to be tried in patients with paroxysmal tachycardia

Effect on the Heart and Vessels

Vagal stimulation decreases the irritability of auricular muscle; an ectopic focus of impulse formation may be eliminated and normal sinus rhythm

drugs are the most commonly used therapeutic procedures in patients with paroxysmal supraventricular tachycardia.*

REFLEX VAGAL STIMULATION

In man, reflex stimulation of the vagus nerve (Table 1), which is the simplest and safest procedure in paroxysmal supraventricular tachycardias, can be readily carried out by the physician and, with the exception of apomorphine, by the patient. After such stimulation the cardiac effect appears quickly and is of short duration. Further-

resumed. Vagal stimulation also slows the rate of the normally beating heart by an action on the sinoauricular node, and slows the rate of impulse conduction from auricle to ventricle, as a consequence, cardiac standstill nodal rhythm and partial or complete auriculoventricular block may be observed.

The sinoauricular and auriculoventricular nodes in man are each innervated by both the right and left vagus nerves. Some observers²⁵ have noted that sinoauricular asystole occurs more often with pressure on the right than on the left carotid sinus (that is, right and left vagal stimulation), whereas auriculoventricular block occurs more often with pressure on the left side. In other studies,⁴⁰ how-

*The term supraventricular as used here denotes tachycardias arising in the auricle or in the auriculoventricular node.

ever, no predominance of sinoauricular-node or auriculoventricular-node depression as a consequence of pressure on the right or left carotid sinus was seen. There is no evidence, moreover, for the superiority of either right or left reflex vagal stimulation in stopping supraventricular tachycardia. Indeed, the importance of stimulating both carotid sinuses in each case has been stressed.⁴¹ It is of interest that direct mechanical stimulation⁴² of the vagus nerve does not slow the normal heart, nor is electrical stimulation effective in persistent sinus tachycardia.⁴³

Nonidez,⁴⁴ in demonstrating parasympathetic nerve supply to the sinoauricular node, auricular muscle, auriculoventricular node and coronary vessels, found that parasympathetic nerve fibers did not appear to innervate ventricular musculature. These findings are in keeping with observations that carotid-sinus pressure usually has no effect on ventricular arrhythmias.⁴⁵⁻⁴⁷

Although vagal stimulation, by way of carotid-sinus reflexes, may induce a fall in blood pressure and a change in heart rate and in cardiac output, all affecting the coronary circulation, the exact action of vagal stimulation on the coronary arteries and coronary blood flow in man is not known.⁴⁸

METHODS OF PRODUCING REFLEX VAGAL STIMULATION

Carotid-Sinus Reflex

Anatomy The carotid sinuses are slight bulbar enlargements of the internal carotid arteries at the bifurcation of the common carotids, sometimes involving the junction of the common and the internal carotid arteries.

Physiology Variation of pressure within the carotid sinus produces prompt changes in systemic arterial pressure and heart rate, the impulses for the cardiac effects being transmitted over efferent vagus pathways.⁴⁹ Increased pressure within the carotid sinus induces reflex vagal stimulation and simultaneous inhibition of the tonus of the cardio-accelerator nerves. Although the largest accumulation of pressoreceptor fibers is in the carotid sinus, sensitive fibers are also present in the walls of the common, internal and external carotid arteries for a short distance above and below the carotid sinus.⁵⁰

Means of production Digital pressure on the carotid sinus is first performed with the patient supine, the neck extended by means of a pillow elevating the shoulders, if necessary, and the head slightly rotated away from the side of the carotid sinus to be stimulated. With the physician preferably behind the patient, one of the carotid sinuses is located. It can often be felt as an expansile body situated at the angle of the jaw, usually at the level of the thyroid cartilage, although it may be ectopic. Frequently, it is impossible to feel the actual bulbous enlargement, and one must be guided by the point of maximal carotid pulsation. The greatest

difficulty is experienced in patients with short, thick necks.

Pressure is applied toward the vertebral column by vigorously rubbing with several fingers over the carotid sinus and several centimeters above and below. Engel and Engel⁵¹ emphasized the importance of retracting the carotid artery laterally to prevent the vessel from slipping medially. The heart rate should be observed continually during the period of pressure, and, if there is any change, the pressure stopped immediately. Patients themselves not infrequently learn to terminate attacks of paroxysmal supraventricular tachycardia with carotid-sinus pressure. The duration of pressure is short, and the patients are able to recognize the termination of the attack by the cessation of symptoms. If the heart rate is not affected, pressure may be continued for approximately ten seconds. If pressure applied separately to the right and the left carotid sinuses of the recumbent patient does not stop the arrhythmia, the procedure may be more effective with the patient in the sitting position, or when pressure is applied simultaneously to both carotid sinuses.

Repetition of pressure Failure at one time during the episode of paroxysmal tachycardia of various procedures inducing reflex vagal stimulation does not preclude success with the same measures later in the attack. Several observers⁵²⁻⁵⁵ have emphasized the importance of repeating reflex vagal measures. We have had an instructive experience⁴⁴ with carotid-sinus pressure in stopping attacks of supraventricular tachycardia in a sixty-four-year-old woman with no other evidence of cardiac disease. When untreated, the attacks lasted up to thirty hours. On several occasions pressure on the right carotid sinus was followed by immediate cessation of the attack, although repeated attempts by the same observer during the previous several hours had been ineffective. This variability has been attributed⁵⁶ to differences in the degree of vagal stimulation produced at different times rather than to variation in the susceptibility of the cardiac mechanism. There is, however, insufficient evidence to explain the difference satisfactorily. From a practical point of view it is important to realize that vagal procedures should be tried repeatedly for a time before one resorts to some other form of therapy.

Influence of other agents The favorable influence of the prior administration of acetyl-beta-methylcholine,⁵⁶ neostigmine⁵⁷⁻⁵⁸ and lanatoside C⁵⁹ on the effectiveness of carotid-sinus pressure in the arrhythmias has been noted. Contrariwise, commonly used pressor agents such as epinephrine, benzedrine, paredrine and neosynephrine prevent the cardiac slowing of hyperactive carotid-sinus reflexes in patients with normal sinus rhythm.⁶⁰ However, paredrine and neosynephrine have been employed successfully in the treatment of paroxys-

mal supraventricular tachycardia. Moreover, their use may be required in the treatment of the peripheral vascular collapse observed in some cases of tachycardia.

The relations of quinidine, commonly employed in the treatment of various arrhythmias, to carotid-sinus reflex activity are of interest and importance. In animals, quinidine inhibits the cardiac effect of electrical stimulation of the vagi⁶¹ and of the parasympathomimetic drugs.⁶² Similarly, in man, Nathanson⁶³ found marked inhibition of a constantly hyperactive carotid-sinus reflex after very large doses of quinidine sulfate administered over a period of four or five days. However, the administration of quinidine in smaller but therapeutically effective doses of 0.2 to 0.6 gm. two or three times at two-hourly intervals has been shown⁶⁴ to have no effect on the activity of this cardioinhibitory reflex in 6 patients with angina pectoris. The plasma concentrations were of the magnitude usually seen after these therapeutic doses.⁶⁴

Side effects. Untoward effects such as syncope and convulsions may follow carotid-sinus pressure. These may be observed in patients who have never had a fainting spell or other symptoms suggesting a hyperactive carotid-sinus reflex. They may occur, moreover, in the absence of significant cardiac slowing.⁴⁰ Syncope and convulsions are much more apt to follow carotid-sinus pressure with the patient in the sitting or standing positions or with bilateral simultaneous pressure, they are more likely to occur in elderly patients and particularly in patients with angina pectoris. In elderly patients with generalized arteriosclerosis, prolonged carotid-sinus pressure with complete occlusion of the carotid artery may be followed by transient or permanent hemiplegia.⁶⁵ Shookhoff⁶⁶ describes the occurrence of ventricular fibrillation with cardiac recovery in association with carotid-sinus pressure in a patient with auricular fibrillation. Rarely, precordial pain, wheezing and gastrointestinal symptoms have been observed. These effects are uncommon but indicate the importance of maintaining pressure only as long as is absolutely necessary and, as mentioned above, generally not longer than ten seconds.

Efficacy in treatment of paroxysmal supraventricular tachycardia. The frequency with which carotid-sinus pressure terminates paroxysmal supraventricular tachycardia is not established. Levine⁴⁷ states that auricular tachycardia can "generally" be arrested by one of the procedures inducing reflex vagal stimulation. White,⁶⁷ however, states that reflex vagal stimulation is effective in only 10 per cent of all cases of paroxysmal tachycardia, a great majority of which are supraventricular. In 17 patients, Starr⁶⁸ found that carotid-sinus pressure alone was successful in terminating 16 of 50 attacks (32 per cent).

There is no necessary relation between pre-existent hyperactivity of the carotid-sinus reflex

and the efficacy of carotid-sinus pressure in an episode of tachycardia.

Efficacy in other arrhythmias. Carotid-sinus pressure and other means of reflex vagal stimulation are not significantly effective in other arrhythmias. Although the ventricular rate may be slowed in auricular fibrillation, normal sinus rhythm is not restored. In auricular flutter the increased auriculoventricular block produced by the reflex stimulation may slow the ventricular rate and enable the auricular deflections to be seen more readily in the electrocardiogram. Weiss and Baker⁶⁸ observed temporary change of auriculoventricular-node rhythm to normal sinus rhythm, and we have seen halving of the ventricular rate during carotid-sinus pressure in a patient with auriculoventricular-node tachycardia.

Many case reports testify to the ineffectiveness of reflex vagal stimulation in paroxysmal ventricular tachycardia.⁴⁵⁻⁴⁷ Weiss and Baker,⁶⁸ however, noted instant disappearance of paroxysmal ventricular tachycardia following carotid-sinus pressure.

Summary. Carotid-sinus pressure is a simple and relatively safe means of inducing reflex vagal activity to stop attacks of paroxysmal supraventricular tachycardia. It is the first measure to be tried in all such cases, and, if ineffective, should be repeated at frequent intervals. There are individual variations in the excitability of various vagal reflexes. The absence of an effect from carotid-sinus pressure does not exclude the possibility of a markedly active response from another means of inducing reflex vagal stimulation.

Carotid-sinus pressure has little therapeutic value in other arrhythmias.

Oculocardiac Reflex Induced by Eyeball Pressure

Physiology. In the oculocardiac reflex, afferent impulses are transmitted centrally through the ophthalmic fibers of the trigeminal nerve to connect with the vagal nuclei, where efferent inhibitory impulses are transmitted along the vagus nerve to the heart.⁶⁹ After eyeball pressure, inhibitory effects are observed on the sinoauricular node, the auricular muscle and the auriculoventricular conduction system.⁷⁰⁻⁷¹ These are similar to those seen with other types of reflex vagal stimulation. It has been stated⁷⁰ that pressure on the right eye induces a more marked effect on the sinoauricular node and the auricular muscle, whereas pressure on the left eye leads to greater effect on auriculoventricular conduction. Since the oculocardiac reflex persists during ether anesthesia even after the corneal reflex has disappeared, eyeball pressure may be utilized in the therapy of paroxysmal supraventricular tachycardia during operations.⁴⁷

As with the carotid-sinus reflex, considerable variation in the degree of activity of the oculocardiac reflex is observed from person to person,

and only occasional subjects show what may be termed a hyperactive reflex with high-grade auriculo-ventricular block, asystole and syncope. It is of some interest that hyperactive oculocardiac and hyperactive carotid-sinus reflexes occur in different types of persons and are rarely seen together.^{54, 68, 72, 73} The former is seen most often in young subjects without heart disease, and the latter is seen most often in the older age group and in people with heart disease, particularly angina pectoris. As with carotid-sinus pressure, the efficacy of ocular pressure does not depend upon a pre-existing hyperactive reflex.

Means of production The oculocardiac reflex is excited by pressure with the fingers on both closed eyes just below the supraorbital ridge, and not over the cornea. Firm pressure to the point of pain is applied and continued for twenty-five to thirty seconds. The production of pain does not appear to be a necessary part of the reflex but serves to limit the amount of pressure exerted.

Efficacy in treatment of paroxysmal supraventricular tachycardia A definite relation between eyeball pressure and the cessation of supraventricular tachycardia has been demonstrated,^{6, 47} but the data are insufficient for its efficacy to be compared with that of other methods.

Summary The oculocardiac reflex excited through eyeball pressure by patient or physician is a safe and simple means of producing reflex vagal stimulation. It is a more unpleasant procedure than carotid-sinus pressure and should be tried only after the latter has proved unsuccessful.

Induction of Vomiting

The act of vomiting is a complex phenomenon controlled by the vomiting center in the medulla. There are numerous afferent pathways so that impulses arising in various regions of the body may induce vomiting. Certain emetic agents, such as apomorphine, may act directly on the center. Efferent impulses are discharged over many parasympathetic nerves, often including the cardiac vagal fibers. The degree of cardiac inhibition does not, however, necessarily parallel the intensity of emetic action.⁵⁵ Thus, mechanical stimulation of the mucosa of the pharynx, a simple way of inducing vomiting, has often been tried in paroxysmal tachycardia, but is apparently not so effective as other emetic measures.

Ipecac Since the careful studies of Weiss and Sprague⁵⁶ ipecac has been widely used in the treatment of paroxysmal tachycardia. Each cubic centimeter of the commonly used Ipecac Syrup (U.S.P.) contains approximately 14 mg of the ether-soluble alkaloids of ipecac emetine and cephaline. These substances produce nausea and vomiting by an irritating action on the stomach, as well as by a direct action on the vomiting center.⁷⁴

Method of administration An initial dose of 4 to 8 cc is commonly employed. Nausea and vomiting usually occur within ten to forty-five minutes. If vomiting or reversion to sinus rhythm does not occur, the drug may be repeated in about forty-five minutes. In most cases successive doses should be increased until vomiting occurs, this dose, however, may still be inadequate for the re-establishment of normal rhythm. In such cases Weiss and Sprague⁵⁶ administered more than the minimal emetic dose successfully. Large doses are often followed by nausea and other evidences of parasympathetic stimulation lasting for several hours. The effective single dose varies considerably for different patients, ranging from 4 to 32 cc. Frequently, when the effective dose is established, it can be used subsequently by the patient without hospitalization or medical supervision.

Side effects After oral administration, systemic toxic effects other than weakness and diarrhea are rarely seen, probably because with vomiting the drug is quickly removed from the upper gastrointestinal tract. Weakness, hypotension, sweating, salivation and pallor may accompany the act of vomiting.

Efficacy in treatment of paroxysmal supraventricular tachycardia Successful termination of paroxysmal auricular tachycardia was accomplished in each of 14 patients studied by Weiss and Sprague.⁴⁸ Other methods of reflex vagal stimulation and acetyl-beta-methylcholine, digitalis or morphine had failed.

Summary Ipecac is of definite value in stopping paroxysmal auricular tachycardia. Its beneficial action is necessarily accompanied by vomiting and often by prolonged nausea.

Apomorphine Limited information is available⁷⁵ on the use of apomorphine in the treatment of paroxysmal tachycardia. Apomorphine produces emesis by stimulation of the vomiting center. Vomiting takes place within ten to fifteen minutes of the subcutaneous administration of 2 or 3 mg.⁷⁶ of apomorphine hydrochloride and may occur repeatedly. Central-nervous-system depression may occur, and it has been stated that "the indiscriminate use of apomorphine as an emetic cannot be too vigorously condemned."⁷⁶

In view of the possibly serious nature of the toxicity, the absence of a specific antidote and the paucity of pharmacologic data and information concerning effectiveness, the use of apomorphine in paroxysmal tachycardia does not seem warranted.

Miscellaneous Measures

Procedures inducing reflex vagal stimulation that have been mentioned as being of value in stopping supraventricular tachycardia are listed in Table 1. In the Valsalva procedure, a forced expiration is made with the glottis closed after deep inspiration. In the Müller procedure, a forced inspiration is attempted against a closed glottis after

deep expiration. We know of no data that permit an evaluation of the efficacy of these measures in stopping paroxysmal supraventricular tachycardia. It is our impression, based on our own experience and that of others, that these procedures are much less effective than other means of producing reflex vagal stimulation.

PARASYMPATHOMIMETIC DRUGS

Numerous drugs reproducing the cardiac effects of vagal stimulation have been used in the treatment of paroxysmal tachycardia, usually when reflex vagal stimulation has been ineffective. Parasympathomimetic drugs (choline, carbaminocholine, physostigmine and pilocarpine) with which there has been very limited experience (Table 1) are not discussed here.

Choline Esters

The choline esters act directly on the effector cells in tissues with cholinergic nerve supply.⁷⁶ Their cardiac effect is qualitatively similar to that of reflex vagal stimulation. The choice of a particular choline ester for use in paroxysmal tachycardia involves a consideration of the intensity and duration of the cardiac action, the intensity and duration of the undesirable side effects, the readiness with which these side effects can be controlled with atropine and the effectiveness of the drug in stopping the abnormal rhythm.

Acetylcholine Segers and his co-workers,⁷⁷⁻⁷⁸ reasoned that since experimentally induced paroxysmal tachycardia in animals can be stopped by a single induction shock, an agent that produces an intense, although transitory, cardiac inhibition might be of clinical value. Accordingly, they tested acetylcholine in the treatment of paroxysmal supraventricular tachycardia. This drug is characterized by rapid destruction and very short action in the body.

Method of administration and dose An initial dose of 20 mg (1 cc of a 2 per cent solution of acetylcholine chloride in distilled water) was injected intravenously as rapidly as possible. If the attack did not stop, the injection was repeated every three or four minutes with successive doses of 40, 60, 80 and 100 mg; the maximum single dose was 100 mg. To minimize the cerebral effects of the fall in blood pressure following acetylcholine, the drug should be injected with the patient recumbent.

Side effects and contraindications It should be emphasized, in a comparison of acetylcholine with acetyl-beta-methylcholine, that therapeutically effective doses of acetylcholine were well tolerated. Coughing, nausea, a sensation of warmth in the head and palpitation occurred, but did not last longer than a minute. Syncope was not observed and the prolonged alterations in rhythm sometimes seen after acetyl-beta-methylcholine were absent after acetylcholine.⁷⁸

The contraindications to acetylcholine are the same as those for acetyl-beta-methylcholine. Atropine sulfate is an effective antidote and a solution of 0.5-1.0 mg *should be ready in a syringe for intravenous injection before acetylcholine is given*.

Efficacy in treatment of paroxysmal supraventricular tachycardia Segers and his co-workers were able to stop 41 attacks of paroxysmal supraventricular tachycardia in 6 patients. In every case carotid-sinus pressure had been ineffective, and in some acetyl-beta-methylcholine had been without effect. The attacks stopped within thirty seconds of the effective injection of acetylcholine, the interval usually being ten to fifteen seconds. In several cases when the tachycardia recurred very soon, a second injection resulted in definite arrest of the attack. Of practical importance is the fact that the effective dose was found to remain the same for the same person in repeated attacks. Accordingly, once this amount is determined, it can be given as the first dose if the tachycardia recurs.

Similar successful therapy in 5 patients had previously been reported by Abbott,⁷⁹ using single doses of 100 mg intravenously.

Summary Acetylcholine appears to be effective in the treatment of paroxysmal supraventricular tachycardia, and its side effects appear to be less marked and of shorter duration than those of acetyl-beta-methylcholine. Further clinical trial of this drug would be of considerable interest.

Acetyl-beta-methylcholine Since the studies of Starr and his co-workers⁸⁰⁻⁸² acetyl-beta-methylcholine has become the most commonly used parasympathomimetic compound in the treatment of paroxysmal tachycardia. It is a potent, long-lasting choline ester, slowly hydrolyzed by cholinesterase and readily blocked by atropine.

Method of administration Careful observation and considerable skill are required to control the vigorous action of acetyl-beta-methylcholine. The drug is administered subcutaneously with the patient supine, to minimize the cerebral effects of the fall in blood pressure induced by the drug. An effect may be expected in one or two minutes. After subcutaneous administration, the intensity of action can be increased by massage of the injection site and decreased by the application of a tourniquet above the site. The action of acetyl-beta-methylcholine can be blocked by the intravenous injection of 0.5 to 1 mg of atropine sulfate, *the latter should be available in a syringe before the drug is administered*. Preparation for the occurrence of vomiting and involuntary defecation is advisable.

Dose The effective dose of acetyl-beta-methylcholine chloride varies from 2.5 to 60 mg, averaging about 25 mg. Young people react more vigorously to the drug than older ones, and obese persons seem to require larger doses, 10 to 20 mg may be sufficient in young patients, whereas 50 to 60 mg may be needed in older obese patients. The

initial dose of acetyl-beta-methylcholine chloride should be 5 to 15 mg, a larger dose may be given in fifteen to twenty minutes when the effects of the preceding one have worn off

Acetyl-beta-methylcholine should not be administered intravenously We have observed generalized convulsions, and syncope due to cardiac standstill has been reported,⁸² after the intravenous administration of 20 to 30 mg. If intravenous administration of atropine is not possible because of convulsions, it should be given intramuscularly

Side effects and contraindications The therapeutic effect of acetyl-beta-methylcholine on the heart is accompanied by other manifestations of parasympathetic stimulation. There may be flushing of the face and neck, generalized sweating, salivation, lacrimation, increased depth of respiration, fall in blood pressure, epigastric discomfort, nausea, vomiting and involuntary defecation. Substernal pain indistinguishable from that seen in angina pectoris has been observed. These effects are abolished by the administration of atropine sulfate. Death has been reported in several cases^{79, 83} after the administration of acetyl-beta-methylcholine, in none of these was atropine given.

The drug should not be administered to patients with bronchial asthma, angina pectoris or acute or healed myocardial infarction. Vagal stimulation in such cases may induce attacks of asthma, cardiac pain, syncope or convulsions. In patients with hyperthyroidism, acetyl-beta-methylcholine may induce auricular fibrillation.⁸⁴

Efficacy in treatment of paroxysmal supraventricular tachycardia Starr⁸⁵ reported restoration of normal sinus rhythm in 66 of 75 attacks of paroxysmal supraventricular tachycardia after one or two doses of acetyl-beta-methylcholine. Others have also reported the efficacy of this drug.⁸⁶⁻⁸⁷ In a number of cases carotid-sinus pressure, which had previously been ineffective, apparently terminated the tachycardia when applied after the administration of the drug.⁸⁸ Continued efficacy was noted in a patient with recurrent paroxysmal auricular tachycardia who received 40 injections during a twenty-month period.⁸⁶

It has been suggested⁸⁶ that, in some patients, failure of acetyl-beta-methylcholine therapy may be related to prior administration of quinidine. This, however, has not been established.

Efficacy in other arrhythmias Paroxysmal auriculoventricular-node tachycardia has been successfully treated with acetyl-beta-methylcholine⁸⁸, after various means of reflex vagal stimulation had failed, attacks were stopped within fifteen minutes in a six-year-old child in whom eight previous attacks had lasted two to fourteen days. The drug is of no therapeutic value in auricular fibrillation,⁸⁶ auricular flutter⁸⁶ or ventricular tachycardia.⁸⁹ Starr⁸⁶ reports an interesting and well controlled observation of the action of the drug subcutaneously

and by mouth in reducing the frequency of spontaneous ventricular extrasystoles. The drug also reduces the frequency of epinephrine-induced ventricular extrasystoles in man.⁹⁰

Summary Acetyl-beta-methylcholine is effective in the treatment of paroxysmal supraventricular tachycardia. Its potent action must be carefully controlled by attention to the dose, the route of administration and the rate of absorption, its antidote, atropine, should be immediately available.

Neostigmine

Neostigmine inhibits the breakdown by cholinesterase of acetylcholine formed in the body.^{90a} Its action on the heart as well as on smooth muscle and glands is abolished by atropine.

Method of administration and dose The effective dose in the treatment of paroxysmal supraventricular tachycardia is 0.5 to 1.0 mg of neostigmine methylsulfate, which may be administered subcutaneously, intramuscularly or intravenously. With intravenous injection the onset of action is very rapid, and after subcutaneous or intramuscular administration the beneficial response and maximum effect upon the cardiac rate occur within twenty minutes. Oral administration of neostigmine bromide, 15 mg three times daily, has been stated to be useful in preventing attacks of paroxysmal auricular tachycardia.⁹¹

Side effects and contraindications Mild degrees of nausea, abdominal cramps, eyelid twitching, sweating, lacrimation and salivation have been observed after the subcutaneous or intramuscular administration of 0.5 to 1 mg of neostigmine methylsulfate. This evidence of parasympathetic activity may persist for 30 to 60 minutes and is usually not so severe as to require treatment with atropine. Gastrointestinal symptoms, cramps and diarrhea have occurred after the daily oral administration of 15 to 45 mg.

Death has been reported recently⁹² in a patient given 0.5 mg of neostigmine methylsulfate intramuscularly in a test for myasthenia gravis. However, the rarity of this has been emphasized,⁹³ and the drug appears to be relatively safe even when given intravenously.

Contraindications to neostigmine are the same as those for the choline esters, and atropine is an effective antidote.

Efficacy in treatment of paroxysmal supraventricular tachycardia. Numerous observers^{2, 57, 58, 91, 94, 95} have reported the effective use of neostigmine in stopping attacks of paroxysmal supraventricular tachycardia. In many cases carotid-sinus pressure had previously been ineffective but apparently terminated the tachycardia when applied after the administration of the drug.

Summary Neostigmine is a useful and safe drug for the treatment of paroxysmal supraventricular

tachycardia The data are insufficient to compare its efficacy with that of other available agents

SUMMARY OF THE MEANS OF VAGAL STIMULATION

Reflex stimulation of the vagus nerves to the heart or pharmacologic reproduction of the effects of such stimulation are of value in the treatment of attacks of paroxysmal supraventricular tachycardia. Carotid-sinus and eyeball pressure are simple and safe means of reflex vagal stimulation. Although it is possible to obtain a parasympathomimetic effect on the heart or to potentiate reflex vagal action by means of pharmacologic agents, their use also introduces the possibility of undesirable side effects. Thus, vomiting and prolonged nausea are observed after ipecac. Acetyl-beta-methylcholine is the most widely used of the parasympathomimetic drugs, it is not at all certain, however, that other substances may not be at least as effective while causing fewer side reactions. Acetylcholine and neostigmine, particularly, should have more extensive clinical trial from this point of view.

(To be concluded)

BENJAMIN CASTLEMAN, M D, *Associate Editor*

EDITH E PARRIS, *Assistant Editor*

CASE 35411

PRESENTATION OF CASE

A fifty-year-old photographer was admitted to the hospital because of a cough and dyspnea.

Some fifteen years before entry during a routine insurance examination he was told "he had something wrong in his chest." A subsequent roentgenogram of the chest was said to show a "pus pocket" in the lower portion of the right lung. At this time he was completely asymptomatic and had no history of previous pneumonia, sinusitis, aspirated foreign bodies or oral operations. Although he continued to feel well he noticed the onset of a hacking cough one to two years after this examination. During the following ten years he suffered increasing numbers of upper-respiratory-tract infections and "chest colds." Each "chest cold" seemed to persist for a longer period than the last, and the associated cough became increasingly productive of sputum. Six years before entry he noted a rather marked change in his condition characterized by dyspnea on slight to moderate exertion. Chest colds were of one to three months' duration, with cough productive of a half to one cupful of yellowish sputum daily. Two years before admission he stopped smoking, with some subsequent decrease in cough and sputum but little change in the amount of dyspnea. Two months before entry a bronchoscopy and bronchogram at another hospital were said to have shown bronchiectasis. Following these studies he felt improved. Coughing was less, and the daily amount of sputum fell to two or three tablespoonfuls, both symptoms being more prominent in the morning. He had had no hemoptysis. Examination of the sputum for tubercle bacilli prior to admission was reported to be negative.

The past history was significant only in that he had had malaria as a child, his last chill having occurred some twenty years before admission.

Physical examination revealed an obese, middle-aged man in no distress, and was negative except for bilateral, basal inspiratory fine and medium rales most marked on the right, with decreased tactile and vocal fremitus over the right lower chest.

The blood pressure was 130 systolic, 80 diastolic. The temperature, pulse and respirations were normal.

The urine was normal. The blood hemoglobin was 15.5 gm, and the white-cell count 11,100, with 58 neutrophils. The blood nonprotein nitrogen was 31 mg and the total protein 7.0 gm per 100 cc, and the prothrombin time 17 seconds (normal, 15 seconds).

In the hospital the patient's condition remained unchanged. Two vital-capacity determinations were reported as 2.0 and 1.8 liters. A culture of the sputum disclosed abundant alpha-hemolytic streptococci, moderate numbers of *Neisseria catarrhalis* and a few nonhemolytic streptococci. An electrocardiogram was normal. A roentgenogram of the chest showed a considerable amount of mottled and linear density in the right middle lobe, with probable decrease in size of this lobe. There was some compensatory emphysema of the right lower lobe. The heart shadow was within normal limits. A roentgenogram of the nasal sinuses was normal.

On the ninth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR F DENNETTE ADAMS: On the basis of history, it seems certain that this patient had some form of chronic progressive bronchopulmonary infection. Whether it was generalized or local can be determined only by physical examination and x-ray studies. One feature in the history appears to be of no little significance: the two to three months' duration of each acute exacerbation. The usual patient with chronic bronchopulmonary infection is subject to repeated acute flare-ups, but in my experience these rarely last as long as three months. In the days prior to sulfonamides and antibiotics one occasionally encountered a single long-standing exacerbation, in recent years thanks to these new therapeutic agents, the acute attacks rarely last longer than a fortnight and are often shorter. If this is a case of recent years, it seems unlikely that the patient would not have had the benefit of the newer remedies.

DR HELEN PITTMAN: The patient left the hospital last Sunday, so it is a very recent case.

DR ADAMS: Then it seems fair to assume that at least during the past nine or ten years he must have had sulfonamide or penicillin therapy, or both. I do not see how he could have escaped it, aware as I am of the generosity with which these agents are dished out. One would suppose that if he had only bronchiectasis, chemotherapy or antibiotic therapy, perhaps supplemented by postural drain-

age, would have held his periods of incapacity, which were due to acute flare-ups, to one or two weeks or less. That these periods of acute trouble were so protracted suggests to me that there must have been an obstructive element in addition. One cannot stand on the diagnosis of bronchiectasis alone.

The physical examination is not helpful. Rales are reported in the lower lobes. On the right, tactile fremitus and vocal fremitus were diminished, but without further information, one cannot draw any conclusions. The report is inadequate. One could say that if there were dullness in this region, ventilation was poor or the pleura was thickened. If hyperresonance was found, compensatory enlargement of the lower lobe or trapped air could be postulated. The quality and intensity of the breath sounds are not mentioned. The same line of reasoning pertains there. With diminished breath sounds one would presuppose thickened pleura or trapped air, with increased breath sounds, compensatory enlargement. Incidentally, the term "compensatory emphysema" is not a good one because the word emphysema implies actual changes in the lung. In so-called compensatory emphysema, no real structural changes are present.

The laboratory examinations are of no additional help. So we now come to the x-ray studies. Will Dr. Wyman lend us a hand?

DR. STANLEY M. WYMAN: There is an area of linear, somewhat mottled density in the right-midlung field, lying rather medially. It is well seen in the lateral view extending anteriorly in the distribution of the middle lobe. There is overaeration of the right lower lobe. The pleura over the right middle lobe is definitely thickened, measuring up to 0.5 cm. The disease in the right middle lobe is well seen in this position. There is no appreciable thickening of the pleura in the right chest elsewhere. The lung fields otherwise appear essentially normal, and the heart is not remarkable. There is a congenital anomaly of the second and third ribs. The picture is quite consistent with a chronic process in the right middle lobe. I cannot see the bronchi well enough to comment on the patency in that region.

DR. ADAMS: The protocol states that there is compensatory emphysema in the right lower lobe. Can you distinguish between that and trapped air?

DR. WYMAN: One could by fluoroscopy.

DR. ADAMS: You can observe that air does not get out of the area?

DR. WYMAN: The lower lobe is diminished in size. The term "compensatory emphysema" was used because the right lower lobe was seen on fluoroscopy to aerate and decrease in size normally. Therefore, we believed that there was no occlusion of the bronchi in that region.

DR. ADAMS: You are sure of that?

DR. WYMAN: Reasonably.

DR. ADAMS: You know that the fluoroscopic note was made.

DR. WYMAN: I observed that myself.

DR. ADAMS: Then I am sure of it too.

It is perfectly obvious that there was a chronic localized process, presumably in the right middle lobe or perhaps in the lower. Unhappily, it is up to me to decide what it was. If this were straight, uncomplicated bronchiectasis, somewhere in the past history one would expect a report of a severe acute respiratory infection or one of the other episodes mentioned in the protocol. The patient recalled no inhalation of a foreign body, that does not exclude the possibility, however. Bronchiectasis due to whooping cough, influenza or other acute respiratory infection occurring in childhood would probably have developed during youth or early adult life. In such a case failure to recollect the occurrence of the disease in early childhood would not be surprising, and the history might then be regarded as unreliable. The patient was fifty years old when he came to this hospital. If the history is correct, he was approximately thirty-five when the first indications of trouble were discovered and forty when the earliest symptoms appeared. Consequently, it seems reasonable to suppose that he would have remembered any respiratory infection occurring, say, in his twenties or thirties that might have precipitated the present trouble. One must therefore add something to the diagnosis of bronchiectasis. I believe that the something-to-add is bronchial obstruction, with secondary infection and bronchiectasis distal to it. It could have been foreign body, but evidence is lacking. A tuberculous lesion of the bronchus is a possibility, but that seems unlikely. Through the years some other manifestation of tuberculosis should certainly have developed. Of the less common pulmonary infections most are generalized, not local. We need not go into the various yeast infections and others. I prefer to stick to the more common. If bronchial obstruction was present and foreign body can be excluded, the most likely diagnosis is tumor. If it was tumor, it was adenoma. Adenoma of the bronchus is slowly growing, it does cause partial obstruction with infection beyond and frequent acute exacerbations. Hemoptysis is common, if the patient had had one or more episodes of frank hemoptysis or even streaking, I would feel more secure in making this diagnosis. I see no reason to introduce bronchiogenic carcinoma, the duration was too long. On the evidence available therefore, I will make the following diagnoses: first, chronic bronchopulmonary infection, secondly, bronchial obstruction with bronchiectasis, and thirdly, the most likely cause of the obstruction, bronchial adenoma.

DR. JOHN T. QUINBY: Do you think that the vital capacity of 2.0 and 1.8 liters was incorrect?

DR. ADAMS: You think it was too low?

DR QUINBY Yes, in view of the fact that the films did not show real emphysema and that the anteroposterior diameter was fairly good. The diaphragm moved well. That is a surprising figure to me.

DR ADAMS I did not spend a lot of time thinking about vital capacity. To me, history, routine examination of the lungs and x-ray study are much more important. I would be interested to know Dr Pittman's opinion. The low capacity could be explained by the fact that when these patients get into trouble, even with relatively small lesions, they reflexly in some way reduce their vital capacity and get dyspnea out of proportion to the degree of actual lung damage.

DR WYMAN Would you consider the possibility of cholesterol pneumonitis in this case on the basis of a chronic process? You do not know that he had bronchial obstruction. The previous bronchogram may have helped, showing no block.

DR ADAMS I cannot discuss that because I do not know anything about it.

DR TRACY B MALLORY Have we had any cases with as long a duration as this?

DR WYMAN We have had some going on for several years, but I do not know about twenty years.

DR MALLORY My impression is that the duration is under five years.

DR WYMAN I am not certain.

DR ADAMS Dr Mallory, can you call on someone else to discuss Dr Wyman's question? I would like to hear about it myself. Incidentally, I suppose that bronchoscopy was done and that the findings were not put in the record.

DR PITTMAN It had been done in another city shortly before he came here.

DR ADAMS If bronchoscopy did not show a tumor, I am vulnerable. Yet often a bronchial tumor can escape the eye.

DR PITTMAN About the vital capacity, I think it was probably correct. Dr Wyman and I discussed the problem of emphysema at some length, because I was amazed when I saw the film. I went over the chest previously and there was no lateral expansion, and I could not make out the left heart border from hyperresonance.

The patient was a very swarthy person. His color was definitely on the cyanotic tint. He had three estimations of vital capacity on three different days and all in the range of 18 to 20 liters. Clinically, I thought he had severe emphysema. Dr Wyman practically sold me the idea that he did not, but he certainly did not aerate his lungs.

DR JAMES B TOWNSEND Can we be told what the recent bronchoscopy showed?

DR ADAMS It is in the record. The only one performed elsewhere showed bronchiectasis. The bronchogram showed the same. Can Dr Pittman or someone else, discuss Dr Wyman's question?

DR PITTMAN Dr Pittman cannot.

DR MALLORY Tell us what you thought when he was in the hospital before operation.

DR PITTMAN There was some difference of opinion. He was a patient of Dr Sweet's, not mine. I saw him with Dr Sweet. He was sent to Dr Sweet specifically for operation, for bronchiectasis. I saw him after admission while he was being evaluated for suitability for surgery. He had a lot of emphysema, a lot of bronchopulmonary infection, with total and irreversible change, and I was opposed to the idea of operating. The vital capacity was tremendously reduced, and he had borderline cyanosis at rest. The history was almost useless. He could not give a history. It really made no sense. What is given in the record is as good as could be obtained. No one believed that it was reliable. My opinion was, that unless he had very definite sepsis in the right middle lobe as indicated from the degree of bronchiectasis and demonstrated by the bronchograms done prior to admission, which I never did see, if he had even half a dozen alveoli in the right middle lobe working, he had better hang on to them.

DR TOWNSEND We had one bronchial adenoma going on for twelve years, and not until the fourth bronchoscopy could a piece of it be removed to make a diagnosis.

DR ADAMS Did that patient have long attacks of acute trouble?

DR TOWNSEND I do not recall. He had tremendous sepsis.

DR ADAMS If this man had two or three attacks a year and all lasted two or three months, he still would not be a rose!

DR TOWNSEND If this is collapsed middle lobe, why does the right border of the heart show that easily? It is not well defined if the middle lobe is totally collapsed.

DR WYMAN It makes a difference whether it is the anterior or posterior segment that is involved primarily. If there is a little air in the anterior medial segment the upper heart border can be seen.

CLINICAL DIAGNOSIS

Bronchiectasis

DR ADAMS'S DIAGNOSES

Chronic localized bronchopulmonary infection, right middle lobe

Partial obstruction of bronchus, with bronchiectasis

Adenoma of bronchus

ANATOMICAL DIAGNOSIS

Lipid pneumonia (paraffinoma) of right middle lobe

PATHOLOGICAL DISCUSSION

DR MALLORY At operation, a very firm, relatively spherical mass was found in the right middle

lobe It was resected When this was cut in the laboratory the consistence was very fibrous, dense, firm and described actually as woody, with a few small gritty areas of calcification in it Microscopical examination showed that the alveoli in many areas were filled with fat droplets, partly intracellular and partly extracellular — all the characteristic changes of a lipid pneumonia of the type seen following inhalation of liquid paraffin There is nothing in the past history to give any lead on that at all It is possible that thirteen years before admission, when he had chronic sinusitis, the patient used a nasal atomizer containing liquid paraffin It was quite popular at that time, but its use has almost disappeared That is the only possible lead that I can see in the history

I will ask Dr Freiman to discuss lipid pneumonia He has seen a great many cases at the Montefiore Hospital In chronic hospitals, where patients have wasting disease, and in mental hospitals, this condition is commoner than in a hospital of this character

DR DAVID FREIMAN Mineral oil, being very bland, is readily aspirated without the patient's being aware of it As Dr Mallory stated, patients with mental disease or varying degrees of dysphagia are particularly prone to aspiration of this oil taken as nose drops or by mouth for purposes of intestinal lubrication However, even patients who do not have such conditions can aspirate oil of this sort over periods quite readily, and the pulmonary picture is very characteristic The alveoli of the lung are filled with macrophages containing large droplets of liquid petrolatum that vary widely in size and displace the nucleus to one side of the cell This appearance is very different from cholesterol pneumonitis, in which the macrophages are filled with fine droplets that do not displace the nuclei The macrophages in lipid pneumonia migrate into the alveolar septums, where many of them disintegrate, releasing oil droplets A marked fibrous reaction develops around the oil, which tends to obstruct the lymphatic channels and further interferes with drainage from the sector The alveolar spaces are frequently lined by crescentic, foreign-body giant cells The stroma is at first very cellular, but as the fibrosis increases the cells tend to disappear, eventually leaving dense scar tissue in which only oil-filled spaces remain — the so-called paraffinoma This oil can be readily demonstrated with appropriate fat stains Foci of calcification are occasionally seen Since the oil tends to be aspirated in small amounts over a long period it is common to find many phases of the development of the lesion in the same case, often within a very small area

DR ADAMS Can infection occur behind this in the peripheral part of the lobe? In other words, was this an obstructive lesion?

DR MALLORY There was some bronchiectasis and some emphysema in this lobe I cannot tell about the others

Are you willing to express an opinion whether or not surgery benefited this patient?

DR PITTMAN I should doubt it very much This man had a very lengthy, stormy postoperative course acute arrhythmia, paroxysmal tachycardia (rate of 160) and probably massive collapse of the right lower lobe, requiring oxygen continuously And yet, eleven days postoperatively, when he was only able to go about an hour without oxygen, he went home, still cyanotic, still dyspneic and still requiring oxygen

CASE 35412

PRESENTATION OF CASE

A sixty-four-year-old gravedigger was admitted to the hospital complaining of shortness of breath

The patient had been seen ten years prior to admission in the Out-Patient Department, where he was treated for a hernia A chronic cough was noted at this time, but a chest x-ray film was normal Twelve months before admission the cough increased and became productive of small amounts of white phlegm Six months before admission he developed rapidly progressive dyspnea, orthopnea and poorly localized chest pain, for which he was digitalized by his physician There was also gradual deterioration of personal habits and increasing confusion that progressed to total disorientation For this reason he was brought to the Emergency Ward five months before admission Physical examination showed a plethoric, cyanotic man, with a blood pressure of 200 systolic, 90 diastolic, moderate confusion and mild left hemiplegia The veins of the neck and upper chest were dilated There were rales at both lung bases and decreased breath sounds over the right lower lobe A +++ pitting edema of both calves was noted Deep tendon reflexes were increased on the left A lumbar puncture was negative An x-ray film of the chest showed linear increased density in the left lower lobe, with a reduction in size of the lobe There was slight blunting of the left costophrenic sinus There was prominence of the heart in the region of the left ventricle and marked tortuosity and sclerosis of the aorta A barium enema was negative An electrocardiogram suggested left ventricular strain or digitalis effect The patient responded well to a low-sodium diet and diuretics or continued digitalization and returned to work, doing heavy manual labor He remained well under maintenance digitalization until two weeks prior to admission, when there was a return of dyspnea and confusion, this time accompanied by excessive perspiration, chills and fever

Physical examination showed distended veins over the neck and shoulder The trachea was in the midline There was flatness over the left lower lobe, with decreased tactile and vocal fremitus and

decreased breath sounds. The lower border of cardiac dullness was percussed 11 cm to the left of the midsternal line in the sixth interspace. The cardiac rhythm was regular, with a Grade II apical systolic murmur. The liver edge was felt 3 finger-breadths below the costal margin, and there was massive edema of the legs and genitalia.

The temperature was 104°F, the pulse 110, and the respirations 40. The blood pressure was 190 systolic, 88 diastolic.

The urine and stools were normal. Examination of the blood disclosed 11.4 gm of hemoglobin and a white-cell count of 2300, with 88 per cent neutrophils, 1 per cent large lymphocytes, 5 per cent small lymphocytes, 4 per cent monocytes and 2 per cent eosinophils, with normal platelets and hypochromic red cells. A blood Hinton test was positive, and a Wassermann reaction was doubtful. The sputum contained gram-positive cocci and gram-negative rods. Abundant alpha-hemolytic streptococci and a few *Haemophilus influenzae* were cultured from the throat. A blood culture was negative. The serum nonprotein nitrogen was 45 mg, and the total protein 6.7 gm per 100 cc, and the chloride 89 milliequiv, the sodium 128.7 milliequiv, and the potassium 5.3 milliequiv per liter.

A chest roentgenogram showed a large pleural effusion obscuring the left leaf of the diaphragm and left-lower-lung field. The heart was either considerably enlarged to the right or was displaced to the right, though the upper mediastinal structures were in the midline.

The patient was put on 200,000 units of penicillin every four hours and 6 gm of sulfadiazine a day. The temperature fell gradually to normal over the next four days, but there was no improvement in other symptoms. On the fifth day, another roentgenogram of the chest showed increase in the pleural effusion and a small amount of fluid on the right. On the seventh hospital day a left thoracentesis was done, with removal of 800 cc of red, cloudy fluid disclosing a specific gravity of 1.012. The centrifuged sediment contained 352,000 red cells and 2760 white cells per cubic millimeter. No tumor cells were found on smear, and the fluid was sterile on culture. On the following day 700 cc of similar fluid was removed. On the eighth day the temperature began to rise, reaching 103°F, and mental confusion increased. The fever persisted, and on the eleventh day there were flaccid paralysis of the left arm and spastic paralysis of the left leg, with extensor plantar response. Respirations became labored, and oxygen was administered. Late that evening a confluent purpuric rash appeared over the lower legs, forearms and flanks. An hour later the patient died quietly.

DIFFERENTIAL DIAGNOSIS

DR MARIAN W. ROPES. In this case, there are three major sites of involvement. As I see it the

problem is to determine the type of involvement in each site, if possible, and then to determine whether any or all are related, the three major sites to my mind being heart, brain and lung. To consider the heart first, the cardiac failure, which eventually was both left and right sided, occurred first six months before admission, responded to treatment and then recurred terminally. It seems probable that the etiology of the heart disease was vascular. I think there are two possible vascular diseases to be considered — namely, arteriosclerotic and hypertensive and periarteritis nodosa. It is difficult to say what part of the cardiac involvement was secondary to the pulmonary disease. I think, probably, in the terminal event this played some role, but there was underlying heart disease of some other type. In this patient, with a positive blood Hinton test, there is one other possibility that must be considered — syphilitic myocarditis. Since this is rare, and does not explain the total picture, I think that it is extremely unlikely in this case.

The second site of major involvement was the brain. Here, again, the deterioration, the confusion and the recurrent paralyses suggest that the probable cause of the brain involvement was vascular. There are three possible etiologies to be considered — arteriosclerosis, syphilis and, again, periarteritis nodosa. I think any one of these three could produce the total picture. There is at least one other possibility that must be considered in this case — namely, metastatic involvement of the brain. However, the long interval of six months, during which I judge he was completely free of symptoms, would be unusual. One might also wonder if the electrolyte disturbance, with abnormal sodium, potassium and chloride, had anything to do with the cerebral symptoms. However, they were presumably not present in the early course, and I doubt that they played a major role in the final illness. They may have been due in part to the fact that he had been on a low-sodium diet for six months.

The third site was the lung. Here, I find it difficult to determine the possible types of involvement causing symptoms. The chronic cough, which was present for ten years before admission, suggests underlying bronchial infection of some degree, and probably an infection played some role in the final illness. The chills, fever and elevation of neutrophils and the response of the fever, at least, to penicillin and sulfadiazine would be in accord with this. Tuberculosis must surely be mentioned in view of the rather long story of pulmonary involvement, but I think that with the total picture that is unlikely.

May we see the x-ray films to get some help in explaining the type of pulmonary disease?

DR JOSEPH HANDELIN. Unfortunately, I have only the films of the present illness. Those taken ten years before admission are not available, and those of the last six months were not given to me.

The films extend over an eight-day period and demonstrate homogeneous obscuration in slightly less than the lower half of the left-lung field. The heart, as said in the protocol, is either displaced to the right side or else enlarged considerably to the right. I cannot be certain. It is apparent that the mediastinum is slightly widened, superiorly. I think part of this results from the superior vena cava, which casts a shadow on the right side superiorly, and there may well be paramediastinal fluid on the left, which accounts for the widening on the other side. There is also visible slight distortion of the tracheal shadow at the thoracic inlet and just within the upper thorax. This could result from an enlarged thyroid gland, or it might possibly be due to metastatic lymph-node involvement. The aerated portion of the left lung is not unusual in appearance, except that the left hilus may be a little lower than it should be. This in turn suggests that there may be obstruction to the left lower main bronchus, with collapse of the left lower lobe, although collapse of the left lower lobe may be due to fluid accumulation alone. Precisely what is occurring, we cannot say because of the obscuring fluid. The right lung is not remarkable except for a moderate amount of fluid at the right base. The last film shows subcutaneous emphysema along the left chest wall following thoracentesis.

DR ROPES: These are helpful to me because, in addition to the fact that there was possibly slight atelectasis six months before, they suggest that there may have been more atelectasis during the terminal episode.

There are several etiologic processes that might be considered. One is syphilis, but since syphilis of the lung is very rare, and this is not a typical picture, I think it can be discarded. Whether or not vascular etiology would explain the picture, I do not know, but it must be considered in view of the evidence of vascular involvement elsewhere. Part of the picture might be explained on this basis but not the early decrease in the size of the lung, which I assume was due to atelectasis. In addition, the bloody effusion could not be explained on such a basis. Pulmonary infarct must be thought of in view of the rather sudden onset of the terminal illness and the bloody pleural effusion. Again, this does not explain the preceding pulmonary disease. I believe that the change in cough that occurred a year before admission and the x-ray changes present six months before admission, suggesting at least atelectasis, the bloody effusion, and probably more collapse of the lower lobe, with the possibility now of even metastatic areas in the mediastinum, are strongly suggestive of tumor.

Having considered the three sites, the question is to decide whether the three involvements can be due to the same process. I think only two possibilities would have to be considered: periarteritis nodosa and syphilis. Periarteritis nodosa can ex-

plain the cardiac and cerebral involvement but, as I have already said, would not to my mind explain the entire pulmonary picture. Syphilis would explain the cerebral picture but probably could not explain either the cardiac or the pulmonary condition. So I think that I must make at least two diagnoses. Of the pulmonary possibilities I would choose tumor as perhaps the most likely. Lymphoma is suggested definitely by the bloody effusion, but the age and probably the type of progression, with early atelectasis, would be against it and would make carcinoma slightly more likely. The cardiac and cerebral involvement were on a vascular basis, presumably arteriosclerotic, although I cannot rule out the possibility that syphilis played a role in the cerebral involvement.

DR TRACY B. MALLORY: I wonder if anyone can tell about the opinion on the wards.

DR J. W. LITTLEFIELD: We believed that the bloody effusion could be due either to carcinoma or to tuberculosis of the lung.

DR HELEN S. PITTMAN: We have a case not yet proved in which bloody effusion was secondary to an intercurrent respiratory-tract infection, not tuberculosis. It seems to be that because it completely disappeared and remained so for a year, and that is fairly good evidence of it. I wondered if the culture of *H. influenzae* from the throat may have been more important than a passing finding.

CLINICAL DIAGNOSIS

Carcinoma of lung, with cerebral metastases?

DR ROPES'S DIAGNOSES

Cerebral arteriosclerosis
Arteriosclerotic heart disease
Pulmonary tumor, carcinoma?

ANATOMICAL DIAGNOSES

Hemorrhagic pericarditis, subacute
Allergic purpura
Acute glomerulonephritis
Arteriosclerosis, aortic, coronary and cerebral, severe
Hypertrophy of heart
Nephrosclerosis, chronic
Cerebral infarctions, multiple small

PATHOLOGICAL DISCUSSION

DR MALLORY: Our autopsy findings were rather surprising. They do not seem to fit into any recognizable, nameable picture, however. There was severe arteriosclerosis in numerous parts of the body. The aorta was extremely sclerotic. The coronary arteries were pipestem in character and narrow. The renal arteries were extremely narrow, both major and intranephric branches. It was noted that the vessels at the base of the brain and circle of Willis were likewise sclerotic. The surprise

of the autopsy was the finding of a very massive, hemorrhagic pericarditis. Four hundred cubic centimeters of hemorrhagic fluid was present, and the pericardium measured 4 mm in thickness and was covered with shaggy exudate. The process had been going on for a long time, since there was a great deal of fibrous thickening of the pericardial wall. Exudate was also present in the left pleural cavity but was not hemorrhagic in character.

Another surprise was provided by the microscopical examination of the kidneys, which showed, besides old lesions obviously based on arteriosclerosis and consistent with some degree of chronic hypertension, a terminal acute glomerulonephritis, which had not lasted more than a period of five or six days. The single nonprotein nitrogen taken was only 47 mg per 100 cc, a few days before death. The combination of pericarditis and nephritis is, of course, a common one, but ordinarily the pericarditis is a uremic manifestation of the terminal stages of nephritis, whereas here, it is obvious that the pericarditis long antedated the terminal period. We found a few small areas of softening of brain, all fresh. Nothing was discovered to explain the terminal paralysis, but perhaps further study of the brain will bring something out. The skin lesions showed extremely intense polymorphonuclear infiltration—enough almost to suggest sepsis, but Dr. Walter Lever has been over the sections and points out that in certain allergic forms of purpura very marked leukocytic infiltration may occur, so marked that the hemorrhage is almost obscured by purulent infiltration. A very careful search through a great many sections failed to show any lesions that would permit a diagnosis of periarteritis nodosa, which would be about the only reasonable way of tying these factors together. We have no such evidence, however, and I think we have enough sections to rule it out. I cannot fit the picture into any of the "group" diseases, and all I can do is list the various findings.

DR RICHARD CLARK Was an electrocardiogram taken in the second entry? Was there anything different from the first entry?

DR LITTLEFIELD I believe no electrocardiogram was taken.

DR MALLORY No significant degree of fibrosis of the myocardium was noted.

DR ALFRED KRANES Was the heart enlarged?

DR MALLORY The recorded weight was 600 gm, partly because of the shaggy, fibrinous pericardial exudate, perhaps 500 gm was the actual heart weight.

DR KRANES Was the enlargement confined to any chamber?

DR MALLORY No, there was diffuse enlargement of all chambers. The lungs showed chronic bronchitis and a moderate grade of old bullous emphysema that we thought was past history and contributed nothing at all to the terminal diagnosis.

DR HANELIN What was the explanation for the bloody thoracentesis?

DR MALLORY It is possible that they tapped the pericardium. Small amounts of fluid were found in both pleural cavities, about 50 cc on each side. This was blood stained, but there was no evidence of pleuritis and it was believed the blood was introduced during the course of the autopsy. The fluid in the pericardial sac was frankly bloody. I think the pericardial effusion would very adequately explain the enlargement of the heart to the right in the roentgenogram. It is the only possible lead.

A PHYSICIAN What was the lesion by x-ray study in retrospect?

DR HANELIN In retrospect the abnormal placement of the heart in the right thorax was due to the enlarged heart and the pericardial effusion. The uniform increased density of the left lower chest resulted from the cardiac enlargement and the pericardial and left pleural effusion.

The films extend over an eight-day period and demonstrate homogeneous obscuration in slightly less than the lower half of the left-lung field. The heart, as said in the protocol, is either displaced to the right side or else enlarged considerably to the right. I cannot be certain. It is apparent that the mediastinum is slightly widened, superiorly. I think part of this results from the superior vena cava, which casts a shadow on the right side superiorly, and there may well be paramediastinal fluid on the left, which accounts for the widening on the other side. There is also visible slight distortion of the tracheal shadow at the thoracic inlet and just within the upper thorax. This could result from an enlarged thyroid gland, or it might possibly be due to metastatic lymph-node involvement. The aerated portion of the left lung is not unusual in appearance, except that the left hilus may be a little lower than it should be. This in turn suggests that there may be obstruction to the left lower main bronchus, with collapse of the left lower lobe, although collapse of the left lower lobe may be due to fluid accumulation alone. Precisely what is occurring, we cannot say because of the obscuring fluid. The right lung is not remarkable except for a moderate amount of fluid at the right base. The last film shows subcutaneous emphysema along the left chest wall following thoracentesis.

rests with the community leaders who sponsor, support and give direction to these miscellaneous campaigns. When they wish correction they can bring it about."

GUIDEPOSTS TO LITERATURE

DR JOHN SHAW BILLINGS assumed the directorship of the medical library of the United States Army shortly after the close of the Civil War. He determined that the library should eventually be the greatest collection of medical works in existence in any one place and began to accumulate material in a wholesale manner.

In 1879 the collection had attained a considerable size, and Dr Billings became convinced that an undescribed collection of research material in Washington would become stagnant and not truly serve the medical profession of the country. He accordingly established the *Index Medicus*, appearing monthly, in 1879 and the next year began the publication of the *Index Catalogue*. The two publications listed all books and monographs and also analyzed all periodicals and serials received by the library, listing them by subjects.

The *Index Medicus* lasted until 1927 through many vicissitudes, largely owing to lack of moral and financial support by the Government, and was finally forced to consolidate with the rival *Index* published by the American Medical Association. It would have been much better for medical scholarship and research if the *Index Medicus* had been continued with adequate support by the Government. These two publications transformed the Library from a local to a national and international status, and much of its great prestige is based on them.

Medical libraries are essential to efficient, economical medical research. Without the means of making known their resources they degenerate to mere collections of books.

Now a crisis has arisen. The continuance of the *Index Catalogue* and the *Quarterly Cumulative Index Medicus* is hanging in the balance. Their future is being determined by the authorities in Washington and Chicago. Their discontinuance

would constitute a calamity, and much of the justly earned prestige of the Army Medical Library would dwindle and the Library would become merely a large local collection of material to be consulted in Washington.

Washington is the logical place for a distribution center for medical literature, and the Government should in the interests of public health and welfare provide the necessary support for these publications.

COMMUNITY HOUSE

METROPOLITAN Boston's United Community Services are to have a permanent home, the final posthumous benefaction of two charitable sisters, Ellen F. and Ida M. Mason. These public-spirited Boston ladies, who lived at the corner of Walnut and Beacon streets in the house that is now the headquarters of the Judge Baker Guidance Center, left, in the disposition of their property, nearly a million dollars to philanthropy. Half this sum was given directly to various health, social and educational institutions in Boston, Newport and the South, the remainder was established in 1929 as the Mason Fund, the income of which was to be distributed to charitable organizations and the principal of which after 1942, might be disposed of in the same way.

This final distribution is about to be effected by the purchase of the present twelve-story building of the Boston City Club, also on Boston's Beacon Hill, for the use of the red-feather organization and other social agencies. Boston, rarely backward in charitable enterprises but often slow in the development of material facilities, will thus acquire a general "community building" as other cities of comparable size possess.

The purchase of this center comes at a propitious moment, only three months after the establishment of United Community Services as a reorganization of Greater Boston's welfare agencies resulting from the Greater Boston Community Survey.

In announcing the transaction emphasis is placed on the fact that the gift of the Mason Fund represents a separate grant for this housing project.

FIRST THINGS FIRST

THE report of the recent Greater Boston Community Survey contained a protest that was not the first to be voiced against the presence of those unco-ordinated fund-raising activities that constitute such a threat to the basic essential services of a community. The complaint has become almost universal that the national power drives, appealing to the emotions of a still generous people, are cutting across the supply lines of the vital locally organized services of all major communities and are threatening their continued existence.

Nor is it only the March of Dimes, the National Tuberculosis League, the American Heart Association, the American Cancer Society, the American National Red Cross and other nationally recognized organizations that are in this fashion and certainly with the best of intentions tapping in on the re-

sources of each community. The number of worthy appeals has grown to the point where rarely is there a moment in which one or more is not in existence, and the now well publicized plea of the community that begged for a "leave us alone week" gains added sympathy.

Basil O'Connor, former president of the American Red Cross—a supercolossal and particularly independent organization—took it upon himself to bring into the open the danger that now threatens the future of all voluntary health and welfare agencies. In his address before the Annual Convention of the Red Cross in June he indicated plainly that compulsion under state control may yet supersede "voluntary association for the alleviation of human suffering."

Such a change in method is actually not at all unlikely to take place even in this country, as it pursues its course toward the condition of a welfare state. The outcome can only be hastened by the nonco-operation of the fund-raising organizations that ignore the equal if not the prior rights of those charities that begin at home.

As the *Journal of the American Medical Association* remarks, in commenting editorially on Mr. O'Connor's speech:

If this nation were to remove from the sphere of voluntary action the whole experience of relief and assistance and transform it into "a massive, mechanical system of invisible deductions and automatic contributions," people would be deprived of the individual exercise of the impulse of generosity.

And yet that is exactly the situation into which the excessive and unco-ordinated demands of a variety of agencies are leading the country in their zeal.

No more than two intensive campaigns should be tolerated by the people of any community. These should be a community-fund drive at one time of year for the local health and welfare organizations, and as remote from this as possible in point of time a combined drive for all the other health and relief agencies.

When the fact is fully appreciated that last year, in addition to the Community Fund drive, ten organized campaigns sought \$12,000,000 in Metropolitan Boston, the statement made in the Survey report may be heeded: "Responsibility

rests with the community leaders who sponsor, support and give direction to these miscellaneous campaigns. When they wish correction they can bring it about."

In announcing the transaction, emphasis is placed on the fact that the gift of the Mason Fund represents a separate grant for this housing project,

and that none of the money raised by the Community Fund's annual campaign is being used in the purchase of the building

CONGRESSES IN SURGERY

THE clinical congress of the American College of Surgeons, to be held in Chicago from October 17 to 21, is of great interest not only because this is the thirty-fifth such congress but also because the program will include the meeting of the Sixth Inter-American Congress of Surgery—the first time the Congress has been held in the United States. The delegates of the latter organization will attend the sessions of the College and will hold their own meetings from October 21 to 23. Headquarters for both congresses will be at the Stevens Hotel.

The program of the College will include the fourth Martin Memorial Lecture, delivered by Sir James R. Learmonth, of Edinburgh, at the Presidential Meeting on October 17. Lord Webb Johnson, of London, president of the Royal College of Surgeons of England, will deliver the Fellowship Address at the Convocation on October 21, when fellowship will be conferred upon several hundred initiates. Operations will be presented in color over television from St. Luke's Hospital during the Congress. The other events will include scientific sessions, official meetings, medical motion pictures, technical and scientific exhibitions and operative and nonoperative clinics in 24 hospitals in the Chicago area.

Between two and three hundred Latin American surgeons are expected to attend the Inter-American Congress, which is also open to fellows from the United States and Canada. The sessions will center around three main subjects: "Acute Cranio-cerebral Trauma," with Dr. E. Jefferson Browder, of Brooklyn, as the main speaker; "Treatment of Injuries in the Region of the Ankle with Complications and Sequelae," with Dr. Harrison L. McLaughlin, of New York City, as the main speaker; and "Pulmonary Carcinoma" with Dr. Evarts A. Graham, of St. Louis, as the main speaker.

The programs of both congresses offer material of interest to all surgeons. The international character of the occasion makes it of particular significance to all who are concerned with medical and surgical care in the United States and abroad.

Andrew H. Brand, 14 years of age, is on exhibition at Louisville, Ky. He weighs 500 pounds, is 5 feet 6 inches tall, 6 feet round the waist and 3½ round the thigh.

Boston M. & S. J., October 10, 1949

MASSACHUSETTS MEDICAL SOCIETY

DEATHS

ADRIANCE — Vanderpoel Adriance, M.D., of Wills-town, died recently. He was in his eightieth year. Dr. Adriance received his degree from Columbia University College of Physicians and Surgeons in 1893. His widow, two sons and a brother survive.

ROLFE — William A. Rolfe, M.D., of Boston, died on September 24. He was in his eightieth year. Dr. Rolfe received his degree from Harvard Medical School in 1890. He was a member of the American Proctologic Society and a fellow of the American Medical Association. His widow survives.

ROWLAND — William D. Rowland, M.D., of Newton, died on July 1. He was in his seventieth year. Dr. Rowland received his degree from University of Michigan Homeopathic Medical School in 1911. He was chief of the eye staff of the Massachusetts Memorial Hospitals from 1925 to 1942. He was professor emeritus of ophthalmology at Boston University School of Medicine and was a member of the American Academy of Ophthalmology and Oto-Laryngology and the New England Ophthalmological Society and a fellow of the American College of Surgeons and the American Medical Association. His widow, a daughter, two brothers and three sisters survive.

ROYAL — Herbert B. Royal, M.D., of Harvard, died on September 14. He was in his eighty-seventh year. Dr. Royal received his degree from Bowdoin Medical School in 1887. He was formerly a member of the staffs of hospitals in Clinton, Concord and Ayer. Two sons survive.

Tuberculosis other forms	8	14	15
Typhoid fever	3	2	5
Undulant fever	2	2	5
Whooping cough	479	209	475

*Five-year median

COMMENT

Diseases above the seven-year median were chicken pox, diphtheria, dog bite, German measles, poliomyelitis and salmonellosis.

Diseases below the seven-year median were bacillary dysentery, malaria, measles, scarlet fever, typhoid fever and undulant fever.

Poliomyelitis reached the highest level ever reported for the month, partly owing to the early seasonal rise in the disease. The proportion of nonparalytic cases is higher than that in any previous epidemic year.

Dog bite reached the highest level recorded for August (1284 cases) but was less than in May and June of this year (1472 and 1644).

Diphtheria was at the highest level for August since 1934.

For the third consecutive month, only 1 case of bacillary dysentery was reported.

Scarlet fever dropped to the lowest level ever recorded for the month of August.

GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Diphtheria was reported from Berkley, 2, Boston, 13, Charlton, 2, Gloucester, 2, Milford, 2, Revere, 2, Somerville, 1, Wakefield, 1, Wellesley, 1, total, 26.

Dysentery, bacillary, was reported from Lowell, 1, total, 1.

Encephalitis, infectious, was reported from Salem, 1, total, 1.

Infections hepatitis was reported from Foxboro, 1, Lowell, 1, Methuen, 1, Worcester, 1, Wrentham, 1, total, 5
Lymphocytic chomeningitis was reported from Fall River, 1, total, 1

Malana was reported from Boston, 1, total, 1
Meningitis, meningococcal, was reported from Boston, 1, Foxboro, 1, Malden, 1, Wellesley, 1, Weymouth, 1, total, 5
Meningitis, pneumococcal, was reported from Sandwich, 1, total, 1

Meningitis, undetermined, was reported from Cambridge, 1, Fall River, 1, Foxboro, 1, North Attleboro, 1, Salem, 1, Stockbridge, 1, total, 6

Poliomyelitis was reported from Abington, 4, Amesbury, 1, Andover, 2, Arlington, 13, Ashby, 1, Attleboro, 3, Anhnrrn, 3, Barnstable, 3, Barre, 1, Bedford, 1, Belmont, 5, Berlin, 1, Beverly, 1, Billenca, 2, Blackstone, 1, Boston, 127, Bourne, 3, Bovlston, 1, Braintree, 2, Bridgewater, 1, Brimfield, 1, Brockton, 12, Brookline, 8, Burlington, 1, Cambridge, 18, Canton, 2, Chelsea, 5, Chicopee, 3, Clinton, 2, Cohasset, 1, Dalton, 1, Dartmouth, 1, Dedham, 12, Dennis, 2, East Bridgewater, 1, East Longmeadow, 1, Everett, 12, Fairhaven, 1, Fall River, 2, Falmouth, 3, Fitchburg, 2, Foxboro, 2, Framingham, 2, Gardner, 2, Georgetown, 1, Grafton, 3, Greenfield, 2, Halifax, 1, Hamilton, 1, Harvard, 1, Haverhill, 4, Hingham, 3, Holliston, 1, Holyoke, 6, Hudson, 4, Hull, 2, Ipswich, 1, Lancaster, 2, Lawrence, 2, Lee, 1, Leicester, 1, Leominster, 6, Lexington, 1, Lincoln, 1, Lowell, 3, Lynn, 25, Lynnfield, 2, Malden, 23, Manchester, 2, Mansfield, 2, Marblehead, 3, Marion, 2, Marlboro, 2, Marshfield, 4, Maynard, 1, Medford, 21, Melrose, 3, Middleton, 2, Mills, 1, Milton, 8, Montague, 1, Natick, 4, Needham, 3, New Bedford, 1, Newburyport, 3, Newton, 24, Norfolk, 1, North Adams, 1, North Attleboro, 3, Northampton, 1, Northboro, 1, Northbridge, 1, Norwood, 11, Peabody, 1, Pembroke, 1, Pittsfield, 3, Plainville, 2, Plymouth, 1, Provincetown, 1, Quincy, 27, Randolph, 1, Raynham, 1, Reading, 1, Rehoboth, 1, Revere, 6, Rochester, 1, Rockland, 2, Rockport, 2, Salem, 7, Salisbury, 2, Sandisfield, 1, Sandwich, 1, Sangus, 3, Scituate, 1, Sharon, 4, Shirley, 1, Somerset, 1, Somerville, 31, South Hadley, 1, Spencer, 1, Springfield, 14, Stoneham, 1, Stoughton, 3, Swampscott, 3, Taunton, 1, Templeton, 1, Tewksbury, 2, Townsend, 1, Truro, 2, Uxbridge, 4, Wakefield, 2, Walpole, 3, Waltham, 11, Ware, 3, Wareham, 3, Watertown, 9, Wayland, 3, Webster, 1, Wellesley, 2, West Newbury, 1, West Springfield, 3, Westboro, 4, Weston, 1, Weymouth, 9, Whitman, 3, Wilbraham, 1, Williamstown, 1, Wilmington, 2, Winchester, 4, Winthrop, 14, Woburn, 8, Worcester, 17, Wrentham, 3, Franklin, 4, total, 725

Salmonellosis was reported from Boston, 4, Brookline, 67, Fall River, 1, Holyoke, 1, Lawrence, 1, total, 74

Septic sore throat was reported from Boston, 4, Free-town, 1, Worcester, 1, total, 6

Typhoid fever was reported from Boston, 1, Haverhill, 1, Middleboro, 1, total, 3

Undulant fever was reported from Millbury, 1, Watertown, 1, total, 2

CORRESPONDENCE

DIVERGENT VIEWS

To the Editor Dr. McManamy's letter in the September 1 issue of the *Journal* is interesting because the very finality with which it disposed of problems pertaining to the every-day practice of medicine paradoxically emphasizes the need of their further consideration.

For instance, should physicians who daily make or avoid decisions pertaining to life and death, happiness and suffering, absolve themselves from professional responsibilities by unquestioningly accepting a judgment pronounced with a totalitarian authority that accords neither with the spirit of science nor with democracy or Christian tolerance? Or is drawing from our minds curtains woven from dogma foreign to our American tradition of individual responsibility essential to the ideals of a profession whose function is to ameliorate human suffering by its knowledge of natural law. In stating that we "give lip service to God as the creator of life" while "we presume to usurp His authority over life,

its beginning, its functions and its end," Dr. McManamy dogmatically prescribes limitations to physicians' services without defining the line between usurpation of God's authority over life and death and service to God and humanity in preventing death and suffering. Under which category is the provision of oxygen to the newborn infant, of penicillin to the young person with pneumonia or of digitalis to the patient with cardiac disease? Must doctors forego their science for Christian Science? Or what physician, who witnesses the suffering of a patient ordained by God to die, can say that withholding the medication that permits a painless passing to eternal sleep is "murder in the first degree"? When we as obstetricians and pediatricians ponder preventing the death of a child who would die but for our efforts and in living will be a burden to family and society, are we usurping God's authority or with intelligent humility serving His will as best we may? Who can say whether Dr. McManamy's freedom from such doubts is as Christian as it is conducive to her peace of mind in avoiding difficult problems by conveniently ascribing them to God's will. Surely this is not good Catholicism.

Finally, must we physicians adopt the almost morbid "idea that the insane and feeble-minded, the sick and the weak offer us a means of working out our salvation" instead of the Christian concept that their misfortune presents a challenge to us to prevent and alleviate suffering? Will religious fervor, like antivivisection sentiment, inhibit physicians in their service to humanity, or will it join with science in enabling us by applying faithfully our ever-expanding knowledge of prevention and curative medicine to extend happiness and lessen suffering?

ALLAN M. BUTLER, M.D.

Massachusetts General Hospital

To the Editor Regarding the letter entitled "First Principles" in the September 1 issue of the *Journal*, a first principle is beware the babble of a bigot. There is no logical basis to the statement that planned parenthood is a euphemistic name for prostitution of marriage.

Let Dr. McManamy practice what she may, but advise her to cast no stones. I, for one, would not use the epithet prostitute lightly.

GEORGE M. BARTOL, M.D.

Milton, Massachusetts

To the Editor For some years I have enjoyed thoroughly the many interesting papers published in your excellent journal. I think one of the most far-reaching and provocative ones in some time is the one in the July 14 issue by Dr. Leo Alexander — "Medical Science under Dictatorship." I think his warnings that we in this country are tempted at times to slide insidiously and perhaps unconsciously into some of the potentially dangerous channels that led to the downfall of German medicine are most timely. I have been much interested in the correspondence called forth by Dr. Alexander's article. Unfortunately, the Spanish Inquisition has been dragged into this discussion. This seems to be as irrelevant as efforts to relate the issue to the burning of Salem witches. On the other hand, the recent letter by Dr. Margaret C. McManamy seems to state the issue rather clearly. I shall not waste time or space repeating her thoughts but merely point out that her discussion of first principles impresses me as a very clear statement to those who wish to build a society on God's immutable laws rather than upon the shifting sands of expediency and convenience.

*Five-year median

COMMENT

Diseases above the seven-year median were chicken pox, diphtheria, dog bite, German measles, poliomyelitis and salmonellosis.

Diseases below the seven-year median were bacillary dysentery, malaria, measles, scarlet fever, typhoid fever and undulant fever.

Poliomyelitis reached the highest level ever reported for the month, partly owing to the early seasonal rise in the disease. The proportion of nonparalytic cases is higher than that in any previous epidemic year.

Dog bite reached the highest level recorded for August (1284 cases) but was less than in May and June of this year (1472 and 1644).

Diphtheria was at the highest level for August since 1934.

For the third consecutive month, only 1 case of bacillary dysentery was reported.

Scarlet fever dropped to the lowest level ever recorded for the month of August.

GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Diphtheria was reported from Berkley, 2, Boston, 13, Charlton, 2, Gloucester, 2, Milford, 2, Revere, 2, Somerville, 1, Wakefield, 1, Wellesley, 1, total, 26.
Dysentery, bacillary, was reported from Lowell, 1, total, 1.
Encephalitis, infectious, was reported from Salem, 1, total, 1.

TREATMENT OF INTUSSUSCEPTION CAUSED BY INVAGINATED MECKEL'S DIVERTICULUM

Report of a Case, with a Review of Experience in a Community Hospital

RAYMOND W. GADBOIS, M.D.,* MICHAEL A. DEAN, M.D.,† AND WILLIAM E. JOHNSON, M.D.‡

WORCESTER, MASSACHUSETTS

SINCE we believe that the experience of a small community hospital is of importance in evaluating surgical statistics, it is hoped that the following report will be of interest, particularly in comparison with reports from larger, more specialized hospitals.

Meckel's diverticulum, first recorded by Lavator, described in 1700 by Littre, labeled a diverticulum by Ruysh and Merv, was further reported by Morgagni and finally recognized as a cause of abdominal complaints by John Frederick Meckel.¹

Embryologically, Meckel's diverticulum results from a failure of the intestine to lose its connection with the yolk sac. Developmentally, failure to lose this connection may lead to the diverticulum or persistent omphalomesenteric duct, or any combination of conditions between the two. Statistically, it occurs in approximately 2 per cent of the general population and somewhat more commonly in the male.

Meckel's diverticulum is of importance because it may become inflamed, hemorrhage, adhere to mesentery or bowel, form a nidus of internal hernias, form the focal point of a volvulus or act as a foreign body causing intussusception. For clarity the complications may be divided into primary, including acute inflammation, peptic ulcer, fecal fistula, tumor formation and chronic inflammation, and secondary, comprising intestinal obstruction due to acute inflammatory adhesions, bands and internal hernias, volvulus or intussusception.

Acute inflammatory changes in Meckel's diverticulum may closely simulate the signs, symptoms^{2, 3} and course of acute appendicitis. The natural history of the individual case may vary somewhat depending on the patency and diameter of the stoma, but it may undergo secondary gangrene and necrosis and result in peritonitis by rupture, much in the same manner as an acute appendicitis. Likewise, acute Meckel's diverticulitis has similar serious complications, such as local abscesses with inflam-

matory adhesions and possible intestinal obstruction.

Heterotopic tissue⁴ in the diverticulum occurs more commonly in association with ileal mucosa than ileal mucosa appears alone. Peptic ulceration in close proximity to heterotopic gastric tissue is a well known complication. More often it manifests itself as gross painless melena, but occasionally it erodes through the serosa and gross hemorrhage into the peritoneal cavity results.

The patent persistent omphalomesenteric duct is often diagnosed by the occurrence of a mucoid discharge from the umbilicus. When the duct is widely patent throughout its length,⁵ it serves as a fecal fistula and, if active, can lead the patient into the physiochemical imbalances of an overactive ileostomy.

Tumors as well as tuberculosis can occur in Meckel's diverticulum.

The most important secondary complication of Meckel's diverticulum is intestinal obstruction, manifested in one of the four following ways:

Acute inflammatory adhesions can give rise to an early acute mechanical obstruction. As in any other acute intra-abdominal process, the natural process of containment plasters mesentery, loops of bowel and omentum over and near the site of inflammation. An acute inflammatory mechanical obstruction can be a natural sequela of this process.

Meckel's diverticulum can directly or indirectly cause internal hernias, either as a persistent band from bowel to umbilicus² or by attachment of the free tip to any portion of the visceral or parietal peritoneum, thus forming bands through which bowel might prolapse and be unable to reduce itself. The herniated bowel may vary from a small portion of a loop to a whole segment of bowel, most often, of course, the small bowel. If untreated, the condition may quickly pass through all the stages of irreducible exter-

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY

A meeting of the Middlesex South District Medical Society will be held at the Mount Auburn Hospital, Cambridge, on Wednesday, October 19

PROGRAM

11 30 a m Business meeting

12 00 noon

Discussion of Rheumatoid Arthritis

"Diagnosis and General Management of Rheumatoid Arthritis" Dr Charles Short

"The Adrenal Cortex and Rheumatoid Arthritis" Dr Theodore B Bayles

"The Orthopedic Management of Rheumatoid Arthritis" Dr Robert Joplin

The above presentations will include discussion of differential diagnosis, measures that the general practitioner can apply in the treatment of this disease, the metabolic effects of hormones and the conservative, as well as the surgical measures, in the prevention and correction of articular deformities

A colored moving picture will be shown of the first patient with rheumatic arthritis treated by Cortisone. The running time of this documentary film will be about ten minutes

1 00 p m Luncheon

SOUTH END MEDICAL CLUB

A meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, October 18, 12 noon. The speaker will be Dr Charles G Hayden, who will discuss Blue Shield and Blue Cross

Physicians are cordially invited to attend

MASSACHUSETTS ASSOCIATION OF MEDICAL TECHNOLOGISTS, INC

The semi-annual meeting of the Massachusetts Association of Medical Technologists, Inc., will be held at the Berkshire Museum, South Street, Pittsfield, on October 22 from 9 a m to 5 p m

PROGRAM

Medical Application of Radioactive Isotopes Arthur A Hagelstein, M D

Laboratory Diagnoses of Parasitic Diseases of the Intestines in Temperate Climates William Kaufman, M D

Counsellor's Report of the American Society of Clinical Pathologists Donald A Nickerson, M D

Bacteriology in the Small Laboratory David Skinner, M D

AMERICAN SOCIETY FOR THE STUDY OF ARTERIOSCLEROSIS

The American Society for the Study of Arteriosclerosis will hold its annual meeting at the Hotel Knickerbocker, Chicago, on November 6 and 7

SALMON MEMORIAL LECTURES

Dr Stanley Cobb, of Boston, will deliver the Salmon Memorial Lectures at the New York Academy of Medicine on November 8, 9, and 10. The general topic of the lectures will be "Emotions and Clinical Medicine"

LIFE INSURANCE MEDICAL RESEARCH FUND

Applications for 1950 grants-in-aid of research on cardiovascular problems will be received by the Life Insurance Medical Research Fund up to January 1, 1950. Support is available for physiologic, biochemical and pathological research that bears on cardiovascular problems, as well as for clinical investigation in this field. Preference is given to fundamental research. It is expected that about \$550,000 will be awarded for these grants

Applications for postgraduate fellowships for training in research in 1950-51 will also be received by the Fund up to January 1, 1950. Preference is given to candidates who wish to work in the broad field of cardiovascular function or disease and to candidates who wish to work in institutions other than those in which they have obtained most of their experience. A doctor's degree (M D or Ph D), or the equivalent, is

required. The annual stipend varies, as a rule being between \$3000 and \$4000, with larger amounts in special cases. At least 12 postgraduate fellowships will be available

New grants and fellowships will become available on July 1, 1950

A number of pre-doctoral fellowships for basic training in research will also be awarded. Details are available on request.

Further information and application blanks may be obtained from the Scientific Director, Life Insurance Medical Research Fund, 2 East 103rd Street, New York 29, New York

*Open to the medical profession

For our purpose, cases can roughly be divided into three groups occurring in infancy, childhood and adult life. Intussusception is relatively common in the first few years of life, and the greatest proportion of cases occur in the first two years of life. Etiologically no satisfactory explanation for the vast majority of cases can be found. Estimates vary, but it is fair to state that approximately 90 to 95 per cent⁶ of intussusceptions in infancy are found to have no mechanical cause. A few are due to Meckel's diverticulum, intestinal polyp, lymphomas and ileal duplications. In older children the greater number of intussusceptions and in adults almost all have mechanical causes.

Intussusception is a mechanical obstruction and its complications are first partial or complete obstruction with the attending pathologic sequelae. Some intussusceptions produce a maximum of symptoms, progress a short distance and are reducible. Some offer a minimum of symptoms progressing rapidly. Cases are reported with spontaneous expulsion of the intussusception rectally. Between these extremes occur the cases that become incarcerated. Owing to compression of blood vessels venous obstruction, extravasation, anoxemia and infarction of bowel occur. Intra-abdominal rupture with resultant peritonitis may follow. Toxemia occurs fairly soon and if the condition is neglected and allowed to progress, death usually ensues. An analogy can be drawn between an untreated intussusception and an untreated strangulated hernia. The complications and results are similar.

Treatment is, of course, recognition and reduction. Lately, there is a renewed interest in non-operative reduction but the vast majority of surgeons prefer operative intervention so that total pathologic damage can be fully evaluated and the necessary corrective measures immediately applied.

CASE REPORT

An 8-year-old boy was admitted to St. Vincent Hospital on October 5, 1948, with a chief complaint of vomiting. He had been well until 4 days prior to admission, when, after eating breakfast, he complained of "pains in the stomach." This did not keep him away from school but he returned home soon and vomited food residue. During the period before admission he had anorexia and vomited 2 or 3 times a day with short bouts of intermittent abdominal pain. During the 4 days his bowels had been regular except for 4 loose bowel movements with no pain and no blood. On the day prior to admission he vomited twice, once in the morning and again at 11 p.m. The abdominal pain had become no worse. He denied chills, fever, cough and muscle aches. At no time did he have any rash, hematuria or dysuria. On admission the patient appeared listless. The skin was dry, warm and pallid. He had no adenopathy. The lungs were clear, and the only positive physical finding was deep tenderness in the left hypochondrium. There was no palpable mass, no spasm and no costovertebral-angle tenderness. Peristalsis was low pitched and sluggish.

The temperature was 99.4°F, the pulse 98 and the respiration 20.

Examination of the blood disclosed a red-cell count of 5,180,000 with a hemoglobin of 100 per cent, and a white-cell count of 15,500 with 78 per cent neutrophils.

The patient was admitted to the pediatric service with a diagnosis of gastroenteritis. Fluids were forced by mouth and overnight he gradually became somewhat distended and had repeated cramping abdominal pain, most severe in the umbilical region and left upper quadrant. At the time of surgical consultation 18 hours after admission the temperature was 99.4°F, the pulse 104 and the respirations 20. He had not been nauseated and had not vomited during the interval since admission. On physical examination he was alert and co-operative and in moderate discomfort. The abdomen appeared slightly distended and was tympanitic throughout. Tenderness was present throughout the abdomen and maximal in the left upper quadrant. Both rectus muscles were spastic, and the spasm increased with paroxysms of pain. Peristalsis was sluggish and barely audible during intervals between pain and moderately high-pitched and tinkling during the pain. Rectal examination was negative, and no abdominal masses were palpated. A

FIGURE 1 Plain Film of the Abdomen

The localization of the distention to the small bowel suggests mechanical obstruction although it is possible for an adynamic ileus to produce this picture.

plain film of the abdomen revealed marked gaseous distention of the small bowel, with one loop extending well into the pelvis (Fig. 1). An x-ray diagnosis of mechanical obstruction was made.

The surgical service suggested decompression and parenteral administration of fluids, believing that the patient had secondary obstruction on a basis of acute appendicitis, or Meckel's diverticulitis.

After treatment according to the method of Ochsner the patient appeared fairly well and was free of pain but passed no flatus or feces. Peristalsis disappeared. He received penicillin, streptomycin and parenteral injection of fluids. A Cantor tube was passed, and his progress followed by x-ray films. On the morning of the 5th hospital day a firm mass was found in the right lower quadrant and demonstrated by x-ray examination (Fig. 2).

The mass was regarded as representing a localized appendiceal abscess. Throughout the 6th hospital day the pa-

nal hernia, except that operative interference is apt to be longer delayed because of the difficulty in establishing the diagnosis

Acting as the hub on a wheel, the diverticulum may cause volvulus of the small intestine

gressive intussusception requiring reduction or resection in the individual case. The type of intussusception may be ileocolic, ileoileocolic or ileoileal in order of decreasing frequency. When reduction is impossible and more radical measures

14	53	F	Diverticulum (incidental finding)	Excision	Recovery
15	8	M	Irreducible intussusception	Resection with end-to-end anastomosis	Recovery
16	31	F	Fibrosed band	Excision	Recovery

By far the most interesting complication is intussusception. Progressive and retrograde intussusception have been reported. Several years ago a comprehensive review recorded only 25 clearly defined cases of obstructing intussusception due to invaginated Meckel's diverticulum

are required, the attending mortality is of serious proportions.

The results of operation in cases of Meckel's diverticulum and intussusception at St Vincent Hospital are shown in Table 1 and 2.

TABLE 2 Cases of Intussusception Seen at St Vincent Hospital from 1930 to December 1, 1948

CASE No	AGE	SEX	TYPE OF INTUSSUSCEPTION	CAUSE	OPERATION	OUTCOME
1	4 mo	F	Ileocolic	Unknown	Reduction	Recovery
2	7 mo	M	Ileocolic	Unknown	Reduction (performed with difficulty)	Death 8 hr after operation
3	7 mo	M	Ileocolic	Unknown	Reduction (performed with difficulty)	Death 4 days after operation
4	10 mo	F	Ileocolic	Unknown	Reduction	Recovery
5	3 yr	F	Colocolic	Unknown	Reduction manually and with enema	Recovery
6	57 yrs	M	Ileoileal	Unknown multiple perforations irreducible	Resection with ileoileal anastomosis and preliminary ileostomy	Death 4 days after operation
7	11 mo	M	Ileocolic	Unknown	Reduction by enema	Recovery
8	79 yr	F	Ileocolic	Adenocarcinoma of cecum	Primary resection, ileotransverse colostomy	Recovery
9	54 yr	F	Ileocolic	Carcinoid of ileum	Resection and primary anastomosis	Recovery
10	42 yr	F	Ileocolic	Carcinoma of cecum	Reduction ileotransverse colostomy	Recovery
11	8 mo	M	Ileocolic	Unknown	Reduction	Recovery
12	4½ mo	M	Ileocolic	Unknown	Reduction	Recovery
13	46 yr	F	Retrograde ileoileal	Carcinoid of ileum	Resection of ileum	Recovery
14	48 yr	F	Colocolic	Adenocarcinoma of cecum	Resection of cecum and ascending colon	Recovery
15	6 yr	M	Ileocolic	Invaginated Meckel's diverticulum	Reduction resection of Meckel's diverticulum	Recovery
16	8 yr	M	Ileoileal	Invaginated Meckel's diverticulum	Resection end-to-end anastomosis	Recovery

More recently, 29 such cases were listed in a series of 610 intussusceptions.⁶ Pathologically, invaginated Meckel's diverticulum occurs as a polypoid mass that can cause partial obstruction, intermittent self-reducing intussusception or pro-

INTUSSUSCEPTION

Intussusception indicates the passage of one segment of bowel into another. It occurs at all ages, varying in frequency and cause at each age period.

DISCUSSION

One of the factors causing a high mortality in patients with irreducible intussusception is the time lost in either hospitalizing the patient or establishing the diagnosis. Later, in our attempts to arrive at a specific diagnosis and in the extensive use of diagnostic aids (x-ray study and so forth), we may on occasion be guilty of what we are sure is just criticism by our older confreres—namely, unwarranted delay in operative exploration.

In this particular case the patient's symptoms were interpreted as being caused by a perforated appendix with peritonitis. He was treated according to the method of Ochsner. When a mass in the right lower quadrant developed, the diagnosis seemed fully established until the mass was noted to move. His abdomen did not distend because of Cantor-tube drainage. There were no physiochemical imbalances, because of adequate parenteral replacement. Toxemia was minimized by intubation, parenteral administration of fluids and antibiotics. When the abdominal mass moved, intussusception was considered, and a barium enema given to establish the diagnosis. Normal barium enema ruled out an enterocolic intussusception. After barium enema, symptoms increased in severity, cramping abdominal pain developed, the patient grew more restless, and the pulse accelerated. In view of the patient's clinical condition operation was considered necessary. At no time had he passed flatus or feces, and no blood was found on rectal examination to aid in the diagnosis. Although the therapeutic triad of suction, fluids and antibiotics without doubt masked the true abdominal picture, their use probably improved the preoperative condition of the patient.

Intestinal obstruction in a child beyond two years of age can be caused by Meckel's diverticulum and should be considered⁷ in differential diagnosis. A history of severe intermittent abdominal pain, vomiting and melena followed by small amounts of bright-red blood is the most reliable diagnostic aid.⁸ Usually, a palpable abdominal mass can be found, although initially it may be small enough to escape detection. With or without the mass the diagnosis should be considered. Later, x-ray proof of intussusception is not being routinely employed^{6,9} because of time lost during the procedure and the fact that a small percentage of cases will not be diagnosed. If the intussusception is an ileoileal one it may be missed, as was true in the case reported above.

Most surgeons believe that the less done, the better in the original reduction. Unless more radical measures are distinctly indicated, they should be deferred to a later operation. Irreducible intussusception is a trying surgical problem, certain to tax the ingenuity and skill of the surgeon and the recuperative resources of the patient. The appalling

mortality attendant upon the established surgical procedures has made surgeons devise newer approaches. Such a change is reflected in the experience of the Boston Children's Hospital⁶ (Table 3).

operatively of secondary bowel obstruction. Miller¹² believes that the type of operation depends upon the circumstances. Many will permit resection and anastomosis, but most often one will be fortunate in being able to perform a successful exteriorization. Barnes¹³ recently suggested a neat extraperitoneal resection, in which a primary serosal layer of sutures is placed between the intussusceptum and intussusciens. The intussusciens is sutured to the peritoneal edges just below the anastomosis. When the peritoneum is closed about this site, an opening is made in the intussusciens, and the intussusceptum is drawn out and pegged at the anastomosis with guide sutures. The intussusceptum is removed with cautery, and an internal hemostatic layer of sutures is placed. With the guide sutures as countertraction, a small catheter is threaded back into the small bowel proximal to the anastomosis. This serves as an immediate ileostomy, decompressing the bowel proximal to the anastomosis protecting the suture line. By this means a completely extraperitoneal resection is possible.

patient experienced cramping abdominal pain. The mass moved to the epigastrium and then later was found in the left hypochondrium. The abdomen was soft and nontender, with no tenderness over the mass. The pulse had risen to 132, and a diagnosis of progressive intussusception was made. Barium enema revealed a normal colon and distal ileum. The previously noted mass in the right lower quadrant was absent on x-ray study (Fig. 3).

The patient was returned to the ward for continued observation. During the night he required Demerol for pain. In the morning he was observed during an attack of pain in which he doubled his legs up on his abdomen. However, the abdomen was soft and nontender with the mass again in the right lower quadrant. Operative interference was elected. The preoperative diagnoses were internal hernia, volvulus and omental cyst with ?volvulus.

Dilated loops of small bowel extruded through the abdominal incision. The aforementioned mass was easily

When the specimen was opened, the head of the intussusceptum was found to be an invaginated Meckel's diverticulum (Fig. 4).

FIGURE 3 Roentgenogram of the Abdomen in Which the Soft Tissue Mass Previously Observed in the Right Lower Quadrant Is No Longer Apparent

The small bowel remains distended but slightly less so than on the initial examination. After a barium enema the colon filled easily and normally, and the barium also passed freely into the terminal ileum. The appendix filled in the normal position. No pressure defects could be demonstrated on the bowel, and there was no evidence of disease in the colon.

Postoperatively the patient's convalescence was complicated by peritonitis, which quickly subsided, and he was

FIGURE 2 Roentgenogram Taken with the Tip of the Cantor Tube in the Duodenum

A fairly definite soft-tissue mass is outlined in the right lower quadrant. The small-bowel distention appears less at this time.

found, mobilized out of the right lower quadrant, and proved to be an ileoileal intussusception, the intussusceptum measuring approximately 46 cm. With gentle milking behind the head of the intussusceptum a reduction back to approximately 14 cm from its origin was possible. When greater pressure was exerted, a transverse tear occurred in the serosa. Taxis on the intussusceptum was ineffectual, and immediate resection was considered necessary. The abdominal cavity was packed off. The loop of bowel was brought out on the abdomen and the entire procedure performed extra-abdominally. Viable bowel was selected proximally and distally and divided between clamps with cautery. A primary end-to-end anastomosis with three layers of sutures was performed. The bowel had been sectioned at an angle of about 70° to ensure an adequate stoma, and the little finger could easily pass through the stoma. The site of the anastomosis was determined to be approximately 75 cm from the ileocecal valve.

discharged well on the 13th postoperative day with the wound healed by first intention.

DISCUSSION

One of the factors causing a high mortality in patients with irreducible intussusception is the time lost in either hospitalizing the patient or establishing the diagnosis. Lately, in our attempts to arrive at a specific diagnosis and in the extensive use of diagnostic aids (x-ray study and so forth), we may on occasion be guilty of what we are sure is just criticism by our older confreres — namely, unwarranted delay in operative exploration.

In this particular case the patient's symptoms were interpreted as being caused by a perforated appendix with peritonitis. He was treated according to the method of Ochsner. When a mass in the right lower quadrant developed, the diagnosis seemed fully established until the mass was noted to move. His abdomen did not distend because of Cantor-tube drainage. There were no physiochemical imbalances, because of adequate parenteral replacement. Toxemia was minimized by intubation, parenteral administration of fluids and antibiotics. When the abdominal mass moved, intussusception was considered, and a barium enema given to establish the diagnosis. Normal barium enema ruled out an enterocolic intussusception. After barium enema, symptoms increased in severity, cramping abdominal pain developed, the patient grew more restless, and the pulse accelerated. In view of the patient's clinical condition operation was considered necessary. At no time had he passed flatus or feces, and no blood was found on rectal examination to aid in the diagnosis. Although the therapeutic triad of suction, fluids and antibiotics without doubt masked the true abdominal picture, their use probably improved the preoperative condition of the patient.

Intestinal obstruction in a child beyond two years of age can be caused by Meckel's diverticulum and should be considered⁷ in differential diagnosis. A history of severe intermittent abdominal pain, vomiting and melena followed by small amounts of bright-red blood is the most reliable diagnostic aid.⁸ Usually, a palpable abdominal mass can be found, although initially it may be small enough to escape detection. With or without the mass the diagnosis should be considered. Lately x-ray proof of intussusception is not being routinely employed^{6, 9} because of time lost during the procedure and the fact that a small percentage of cases will not be diagnosed. If the intussusception is an ileoileal one it may be missed, as was true in the case reported above.

Most surgeons believe that the less done, the better in the original reduction. Unless more radical measures are distinctly indicated, they should be deferred to a later operation. Irreducible intussusception is a trying surgical problem, certain to tax the ingenuity and skill of the surgeon and the recuperative resources of the patient. The appalling

mortality attendant upon the established surgical procedures has made surgeons devise newer approaches. Such a change is reflected in the experience of the Boston Children's Hospital⁶ (Table 3).

This serves as an immediate ileostomy, decompressing the bowel proximal to the anastomosis protecting the suture line. By this means a completely extraperitoneal resection is possible.

SUMMARY

The experience of a general hospital with both Meckel's diverticulum and intussusception in all age groups is presented

Attention is called to one of 3 unusual cases, which is reported in detail, with successful resection and primary end-to-end anastomosis

Some features of both Meckel's diverticulum and intussusception are reviewed

THE TREATMENT OF SNAKE-BITE POISONING*

A Report of Two Cases Involving the Copperhead

L A CHOTKOWSKI, M D †

KENSINGTON, CONNECTICUT

IT IS indeed a rare occasion when a physician in New England is called upon to treat a bona fide case of snake-bite poisoning although the same statement certainly cannot be made of the false alarm

The following experience is related not primarily to suggest an ideal routine for handling poisonous snake bites, but rather to call attention to the fact that such cases can occur in New England and to suggest that there should be in the mind of every physician a rational plan for emergency and definitive therapy The opinions of others with extensive experience in this problem are at the same time reviewed

The poisonous reptile in these cases was the copperhead (*Agkistrodon mokasen*). It is a member of the pit-viper family, represented in the United States also by the rattler and the cotton-mouth moccasin, which is not native to New England The only other poisonous North American snake, the coral snake, is also found only in warm climates Although this discussion is limited essentially to matters concerning the copperhead, the bites of these three members of the pit-viper family have much in common In a review of the literature no clinical report of a copperhead bite could be found

CASE REPORTS

CASE 1 R M, a 49-year-old farmer, was seen on June 7, 1947, about 15 minutes after receiving the bite of a snake, which he thought was probably a copperhead He had been picking up kindling wood in a woodland lumber shed when the bite occurred (it was a cold rainy day in the spring, and

the snake had hidden in the dry leaves under the wood pile) He had immediately applied a tourniquet to his forearm tightly enough to prevent the venous flow, but not to occlude the radial or ulnar arterial flow On the dorsal surface of the middle phalanx of the middle finger were two puncture holes about 1 cm apart, and 2.5 cm distal to this were three or four smaller scratch marks A small amount of bloody serum was oozing from the puncture holes The patient had been squeezing his finger in this area hoping to express some of the venom, but apparently only bloody fluid was obtained. At the time he appeared in my office, only 15 minutes after the bite, edema had already developed in the involved finger extending proximally to its base and 2.5 cm or so over the back of the hand

Two criss-cross incisions, about 1 cm deep, were immediately made directly over the puncture holes, and bright red blood was obtained spontaneously and by expression Two similar incisions were made over the edematous area proximally, and blood tinged serum was obtained At this point, some 30 minutes after the occurrence of the bite, the tourniquet was removed because of severe pain in the hand, which was attributed to the tourniquet but in all probability was due rather to the irritating effect of the venom The tourniquet was reapplied a few minutes later, and after about another ½ hour was discarded

Since there was no actual proof of the identity of the snake, a search of the shed was made, and after several pieces of kindling had been removed, a copper-colored snake was uncovered It appeared very lethargic but when teased with a stick struck viciously at it Upon verification of the snake's identity the farmer was removed to the New Britain General Hospital for further treatment While searching for the snake he experienced chilliness and complained of general malaise On admission to the hospital, about 3 hours after the bite, he was given intramuscularly 15 cc of Lyovac, a polyvalent antivenin prepared from horse serum for the treatment of any of the three North American pit-viper bites Three thousand units of tetanus antitoxin was also given prophylactically, penicillin in doses of 30,000 units every 3 hours was started, in view of the extensive edema and the well known possibility of infection in such cases

Two further criss-cross incisions were made proximally on the wrist. No suction was applied to the puncture wounds, which were oozing clear serum In retrospect, thorough suction should have been attempted over the puncture wounds as well as the other incisions, and in this way perhaps some

†Junior attendant in medicine New Britain General Hospital clinical assistant in medicine Hartford Hospital attendant in medicine New Britain Memorial Hospital

of the subsequent edema could have been avoided. No potassium permanganate crystals or other medication was applied locally, nor was antivenin injected locally.

On admission, the vital signs were normal, and the remainder of the physical examination was essentially negative. During the night, however, the temperature rose to 100°F by mouth. The patient felt and looked quite ill. There was considerable nausea associated with about six episodes of vomiting. His main complaint was a rather severe pain in his hand and arm lasting about 48 hours. On the following morning the edema had spread to the elbow, and by evening to the axilla. In view of this, an additional 15 cc of antivenin was given and again repeated a few hours later. On the next day, 48 hours after the bite, the edema had spread to involve the shoulder and was extending laterally down the thorax. This area of edema over the thorax was about 20 cm in diameter and 5.1 to 7.6 cm in depth. The central part was characterized by a yellow and black discoloration, and the peripheral "advancing" border was warm and erythematous, fading on pressure. The left arm measured

On the morning of admission the hematocrit was 51 per cent. The nonprotein nitrogen was 35 mg per 100 cc, and the sedimentation rate 2 mm in 1 hour. The white-cell count was 12,300, with 81 per cent segmented and 2 per cent non-segmented forms, 15 per cent lymphocytes, and 2 per cent monocytes. The hemoglobin was 103 per cent. On the 2nd day the bleeding time was 30 seconds, and the clotting time 3 minutes. On the third day the white-cell count was 6300, with 89 per cent segmented and 3 per cent non-segmented forms, 7 per cent lymphocytes and 1 per cent monocytes, and the hemoglobin 89 per cent. The blood serologic findings were negative. The urine on admission gave negative tests for albumin and sugar and had a specific gravity of 1.024. The sediment contained 0 to 2 pus cells and 10 to 12 red blood cells per high-power field. At the time of discharge there were still 1 to 3 red blood cells and 1 or 2 white blood cells per high-power field in the spun specimen.

CASE 2 J. L., a 19-year-old high-school student, was admitted to the emergency room of the New Britain General Hospital at 12:30 a.m. on May 2, 1949. He stated that about ½ hour before admission he had been fishing in a local reservoir, an area known to be infested with copperhead snakes. While walking about the shore of the reservoir, he felt a sudden needle-like jab in his right ankle. In the darkness it was impossible to identify the snake that had bitten him, but in view of the presence of copperheads in this area and in the absence of a rattle it was assumed that the snake was a copperhead. The patient did nothing in the way of first aid for the bite, reporting directly into the hospital. Being alone, he rode in on his bicycle, the entire trip taking about 20 minutes. While riding his bicycle, he noted pain and stiffness in the ankle and a slight chill sensation, but no shaking chills or prostration.

On admission he appeared anxious and in some discomfort owing to the bite. Examination revealed a well developed, well nourished boy. There were two pin-point puncture wounds, approximately 1 cm. apart, situated on the inner surface of the right ankle approximately 1 cm. behind the internal malleolus. There was a bloody, serous discharge from both wounds. There was also at this time, approximately 20 minutes after the bite, swelling, redness and tenderness of the entire ankle extending upward to about 7.6 cm. above the malleolus. Palpation in the popliteal space was slightly tender, and there was tenderness extending up the inner aspect of the thigh to the groin, where the lymph nodes were slightly enlarged and also tender.

The temperature was 98.6°F, the pulse 78, and the respirations 20. The blood pressure was 118/60.

Examination of the blood showed a hemoglobin of 92 per cent (14.4 gm) and a white-cell count of 11,300, with 68 per cent segmented and 11 per cent nonsegmented forms and 21 per cent lymphocytes. The urine had a specific gravity of 1.024, with negative tests for albumin and sugar, and the sediment contained 0 to 1 pus cells and 0 to 1 red cells per high-power field. The prothrombin time on the morning of admission was 100 per cent of normal (16 seconds), and the sedimentation rate 4 mm. per hour. The blood serologic findings were negative. The nonprotein nitrogen was 42 mg per 100 cc.

On admission to the emergency room, a tourniquet tight enough to prevent venous return was placed about the patient's thigh, and two linear incisions about 2 cm. in length were made over both puncture holes. These incisions were then irrigated with saline solution and were suctioned thoroughly for about 15 to 20 minutes hourly for the next 10 hours. The tourniquet, which at first had been applied at the thigh, was reapplied at the ankle just above the line of edema. After an intracutaneous test for horse serum sensitivity, to which the patient was negative, 15 cc. of polyvalent snake serum was injected intramuscularly. At the same time he was given 3000 units of tetanus antitoxin, 1 cc. of penicillin in oil (300,000 units) was given twice daily during the period of hospitalization. Pyribenzamine, 50 mg., was given four times daily. On admission the right ankle was 50.5 cm., the left ankle 27.9 cm., the right calf 36.8 cm., and the left calf 36.2 cm. in circumference on the following day respective measurements were 28.6, 27.9, 36.8 and 36.8 cm. On the leg itself, which was kept flat, there appeared a yellow-blue, very tender discoloration along the lymphatic circulation of the inner aspect of the calf and inner aspect of

FIGURE 1 Film Taken on the Fourth Day in Case 1, Showing Edema of the Left Arm and Thorax

5.1 cm. larger in circumference than the right at the mid-forearm, 6.3 cm. at the elbow and 7.6 cm. at the mid-arm (Fig. 1). On the next day, the edema of the arm had begun to subside, and the arm was only 1 cm. larger at the mid-forearm, 3.8 cm. at the elbow and 3.2 cm. at the mid-arm. Associated with the edema was an exquisite tenderness and swelling of the epitrochlear nodes noted on the evening of admission, followed by tenderness in the axillary nodes, which were still tender even at the time of discharge on the 5th hospital day. About 96 hours after the bite, the edema of the thorax had descended to the crest of the ilium, gradually disappearing on the next day. No gangrene or slough appeared at any time, although two 1.5-cm. blisters filled with amber-colored fluid developed on the bitten finger. Edema could be detected in the involved forearm for about 3 weeks, and in the afflicted finger for about 5 weeks after the bite.

The arm was maintained on two pillows, and the patient lay in a recumbent position as tolerated. He was up and about on the 4th hospital day.

The temperature remained elevated at 100°F by mouth for 3 days, becoming normal on the 4th; the vital signs otherwise remained normal throughout. The blood pressure was 130/80, the pulse 70, and the respirations 20.

Supportive treatment was minimal, consisting of hot wet magnesium sulfate packs to the hand, Benadryl three times a day for 2 days, and a regimen of forced fluids.

On the 8th day after discharge, a mild serum sickness, characterized by urticaria and nausea, appeared and was treated satisfactorily with antihistamine drugs.

the thigh. This discoloration gradually became darker but less tender in the next 48 hours.

In view of the benign course that the patient was running, he was discharged from the hospital on the 3rd hospital day approximately 60 hours after admission.

At home he was allowed to be up and about, and under this treatment the residual swelling in the right ankle disappeared in about 1 week. The discoloration along the lymphatics lasted approximately 2 weeks. When last seen in the office, approximately 3 weeks after the bite, the patient felt entirely well, and the leg appeared normal. There was a moderate urticarial serum-sickness reaction 1 week after injection of the serum.

DISCUSSION

In New England only two types of poisonous snakes are found, the copperhead and the rattlesnake, both members of the pit-viper family.¹ The term "pit" refers to a small hole on either side of the skull just in front of the eyes. The copperhead introduces its venom into its victim by way of two "hypodermic" fangs situated on the upper jaw. These lie folded flat up against the roof of the mouth when the mouth is closed, but project directly forward on a hinge-like arrangement when the mouth is open in the act of striking. These fangs are approximately 1 cm long and are partially covered by the mucous membrane of the mouth, which peels off the teeth when the mouth is stretched open. In addition to these two fangs, there are rows of teeth on the upper and lower jaws. Although an accurate bite pattern could not be made out in the cases reported above, the two fang marks could be seen very plainly. The marks made by the lower teeth in Case 1 were also noted, but these could not be counted individually. For practical purposes, if the fang marks are absent, one can guess that either the snake was not a member of the pit-viper family — and hence, in New England, not a poisonous snake — or, less likely, the bite was superficial and no venom was injected into the victim. This point may be of major diagnostic significance when the true identity of the snake is unknown.²

Once the fact has been established that one is actually dealing with the bite of a venomous snake, the treatment falls into four general phases — namely, first-aid therapy, the use of antivenin, the prophylaxis of infection and the application of general supportive measures. It seems that prompt first-aid management is of considerable importance in the prognosis of these cases. Ideally, the limb is placed at rest in a dependent position, a tourniquet lightly applied proximal to the bite, and immediate incision and suction of the incision performed as soon after the bite as possible.^{3, 4} This method has been accepted for years, one of the first reports appearing in the literature in 1927.⁵ Multiple incisions and suction should be made in a staggered fashion, circling the limb at higher levels as the edema advances. It is the opinion of some authorities^{3, 5} that most patients are undertreated, and few, if any, overtreated. It is suggested that in a severe bite, 50 to 100 small incisions be made

and suction continued for twenty minutes every two hours for thirty-six hours.³ The tourniquet is applied lightly, since absorption of the venom is by way of the lymphatic rather than, primarily, the venous system. The copperhead bite however, usually does not appear to be fatal in adults, and such vigorous treatment may probably be deferred.

Other local therapy such as the use of potassium permanganate crystals no longer seems indicated.

A polyvalent antivenin derived from horse serum and said to be effective for all North American poisonous snakes, except the coral snake, should be given immediately in the usual 15-cc dose. It is suggested by some workers that five, ten or even fifteen doses be used in severe bites and that a single 15-cc dose is practically of no value. (Strangely enough, however, it is believed by others that the life-saving property of this antivenin is due to the gas-gangrene antitoxin that is produced in the horse inoculated with the venom of the snake presumably containing the gas bacillus, rather than to the antivenin factor itself.) In children, since the body weight is less and the concentration of venom per kilogram thus greater, a larger dose of antivenin is necessary than in the adult. It goes without saying that since antivenin is a product of horse serum, its administration should be preceded by the usual test for sensitivity. Antivenin may be administered subcutaneously, intramuscularly or, if symptoms are severe, intravenously. It is preserved in a powdered state and must first be dissolved in distilled water. If the patient is seen within the first two hours, half the initial dose — that is, 7.5 cc — should be injected locally. The amount of antivenin in one 15-cc ampoule is said to neutralize the amount of venom necessary to destroy 50 pounds (22.6 kg) of body weight.⁶ On the basis of this ratio it seems that three or four ampoules contain sufficient antivenin for the ordinary case. The patient in Case 1 received three ampoules, and the patient in Case 2 only 1 ampoule. After bites from rattlesnakes and larger moccasins, in general, a larger dose is indicated.

The use of antibiotics — as in this case, penicillin — is indicated in the prophylaxis of secondary infection. Tetanus antitoxin is also indicated in view of the frequent occurrence of tetanus following snake bites.⁶ Wet dressings are suggested for ulcerative areas that may develop.

General supportive care consists chiefly in the treatment of shock, if it occurs, with the use of blood or plasma, preferably blood. Since many patients have experienced either vomiting or diarrhea, fluid and electrolyte balance must be adjusted. Hemolytic anemia in severe rattlesnake bites may produce a drop of 2,000,000 in the red-cell count.⁶ In Case 1 the drop in hemoglobin was ascribed to the effect of dehydration and subsequent hydration. No hemoglobinuria or jaundice was noted, although hematuria apparently due to renal irritation did

occur. As noted in the case reports, these patients required a minimum of supportive care.

The most striking evidence of a pit-viper bite is the characteristic edema, usually painful, which develops almost immediately after the bite. This is due to the effect of the injected venom. Copperhead venom is an albuminoid, the exact chemical nature of which is unknown. It is a violent irritant, producing a proteolytic and cytolytic effect on the tissues locally and a hematotoxic or hemolytic effect on the red blood cells systemically. Although this venom is eventually absorbed into the lymphatics, the course of the edema suggests that its circulation and movements through the tissues occur primarily by way of the tissue spaces. This supposition of "drifting" of venom is justified on the basis of observation of these and other reported cases⁴ of pit-viper bites that the edema readily ascends above known levels of communicating lymphatics — that is, into the shoulder girdle and chest wall in cases of snake bites of the hand — instead of converging into the axilla. In view of the obnoxious characteristics of this venom one might certainly hesitate before using mouth suction in removing it from the puncture wounds, particularly in the presence of gingivitis or similar oral lesions. The application of a square of rubber over the bite to protect the mouth has been suggested in emergencies. (Facial bites by the Habu snake of Okinawa in one case recently reported caused edema of the respiratory passages and respiratory embarrassment.)

Although the emergency treatment in Case 1 was inadequate, at least so far as suction was concerned, at no time in retrospect does it appear that the patient's life was in jeopardy. Statistics prepared by the Antivenin Institute of America⁷ indicate that the yearly number of poisonous snake bites in this country may amount to 2000 or 3000, the death rate varying from 10 to 35 per cent. Over a twenty-year period ending in 1945, there were 2385 deaths from poisoning by venomous animals in the United States, and only 9 of these were in Connecticut, where this bite occurred.⁸ These deaths include bites of spiders, centipedes and snakes of all types, and no current list of the number of fatal snake bites or of the number of deaths specifically due to the copperhead exists. In New England over a period of the last five years, there were 6 deaths due to venomous animals, none occurring in the relatively snake-free states of Maine and Vermont. Although little information could be found regarding the mortality due to copperhead bites per se, one

gathers that in adults the mortality should be negligible.

SUMMARY

The clinical course and treatment of 2 cases of poisonous snake bite (copperhead) are reported.

Only two poisonous snakes, the copperhead and the rattlesnake, both members of the pit-viper family, are found in New England, the habitat of the two other poisonous snakes in the United States, the moccasin and the coral snake, being warmer climates.

The typical pit-viper bite reveals a pattern of two prominent fang marks and is associated with immediate pain and extensive edema. If these findings are absent the bite can be considered harmless (in New England, that is).

Treatment consists essentially of the early application of a tourniquet, followed by incision and suction and the administration of three or four ampoules of antivenin. Part of this may be injected locally. The dosage varies with the size of the snake and the severity of the symptoms.

Children must be treated more vigorously than adults since the concentration of venom per kilogram of body weight is greater.

Tetanus and secondary infection should be treated prophylactically.

The prognosis for copperhead bites in adults properly treated should be good.

538 Farmington Avenue

BENIGN GASTRIC ULCERS OCCURRING IN THE PRESENCE OF ACHLORHYDRIA*

Report of Two Cases

EIMIR W. HILJERNON, M.D.,† EVERETT D. KIEFER, M.D.,‡ AND MARTIN L. TRACEY, M.D.‡

BOSTON

OVER a period of years there has been a great deal of controversy in the literature regarding the possibility of benign gastric ulcers in the presence of an achlorhydria. Several carefully prepared reports tend to prove that achlorhydria does not exist in the presence of an active ulcer. Palmer and Nutter¹ reviewed 2200 cases of proved duodenal and gastric ulcers in 1940 and found in no case a persistent and total achylia. Bockus² agreed with this in his textbook stating that "true achlorhydria is not found in patients with active peptic ulcer." Washburn and Rozendaal³ reported a series of 906 cases of pernicious anemia, in none of which an ulcer was found. Kahn⁴ also reviewed 840 cases of pernicious anemia without finding any coexisting ulcers.

There has been opposing evidence presented from time to time, such as the paper by Vanzant et al.⁵ in 1933, in which cases of benign gastric ulcers were found in the presence of achlorhydria. Their tests were, however, performed after Ewald meals only. Bockus and Bank,⁶ in 1927, had already shown the value of checking these tests with histamine analysis. Ruffin and Dick,⁷ in 1939, reported a 54 per cent incidence of achlorhydria in a series of 419 cases of duodenal ulcers and a 67 per cent incidence in 42 cases of benign gastric ulcers. However, they used only a single extraction of gastric juice three quarters of an hour after histamine, and the diagnoses were made by roentgenologic examination alone without surgical or microscopical confirmation.

A summary of the objections raised regarding the reported cases of benign ulcer with achlorhydria is as follows: a single test for free gastric acid is inaccurate, the Ewald or Rehfuess test was run for too short a time, a single histamine analysis was made when the sample of gastric juice was taken too soon after the histamine injection, proof was lacking that the histamine used was pharmacologically active, the Ewald or Rehfuess meal test was not confirmed by a histamine analysis, the gastric analysis was not done at the time the ulcer was known to be active, and the diagnosis of benign ulcer was not absolutely confirmed by microscopical examination. Too frequently patients are seen with gastric ulcers that have been diagnosed clinically, roentgenographically and pathologically

(gross) as a benign ulcer only to discover from microscopical examination that cancer is present.

A recent paper by Ricketts and his associates⁸ pointed out that, by definition, the term "peptic ulcer" implies the presence of both free hydrochloric acid and pepsin. It is proved that peptic activity occurs at an optimum hydrogen ion concentration, which requires acid present to attain this concentration. It is also a more or less accepted belief that "peptic ulcers" are caused by the action of acid and pepsin on a mucosa that has been altered in some manner and is now susceptible to this digestive action.

With all these points in mind we consider the following 2 cases worth reporting since both patients had a persistent achlorhydria—by both Ewald meal and histamine tests with the histamine test carried out to seventy-five minutes on each occasion. Clinically, the histamine used in the tests appeared to be pharmacologically active. Both patients had clinical courses indistinguishable from those of patients with benign gastric ulcers (so-called "peptic ulcers"). Pathologically, on gross and repeated microscopical examination, Dr. William A. Meissner found only benign ulceration. In both cases other causes of ulceration of the stomach such as trauma, gastritis of specific origin, syphilis, tuberculosis, foreign body and local vascular disorders, could be excluded, arteriosclerosis was present generally, but no local changes were found in the vessels in the pathological specimens.

CASE REPORTS§

CASE 1. A 69-year-old retired man entered the Lahey Clinic on October 5, 1948, complaining of epigastric pain for a period of 3 or 4 years occurring 3 or 4 hours after meals and sometimes relieved by food and by sodium bicarbonate. There had been times when this pain required morphine by injection for relief. He had never been free from the pain for more than 2 days at a time during this period. His appetite had been poor for the past 4 or 5 months, and he had noted some difficulty in swallowing meat. He complained of belching and flatulency for a period of years, and for the past few months had vomited about once a week. He had had one black stool about 6 months previously, and he had been taking no medication at the time. He complained of constipation over a period of years for which he had been using daily laxatives. A 17-pound weight loss had occurred during the past year.

A review of the systems, past history and family history were noncontributory.

Physical examination revealed that the patient weighed 86 pounds. He was cachectic and pale. There were beginning cataracts of both eyes. The tongue was smooth and fairly

He had no free gastric analysis (free acid recorded as a histamine analysis) was done after an Ewald meal consisting of plain soda crackers and water.

moist, and some senile emphysema was present the posture was poor, and there was coldness of the extremities. Dorsalis-pedis pulses were not obtainable, and moderate peripheral arteriosclerosis was present.

The blood pressure was 130/70, and the pulse 80.

Urinalysis was negative. Examination of the blood disclosed a red-cell count of 4,150,000, with a hemoglobin of 14.1 gm (90 per cent), and a white-cell count of 6900, with a normal differential. The blood sedimentation rate was 23 mm per hour, and the blood Hinton reaction was negative. A stool examination revealed no occult or gross blood. The nonprotein nitrogen was 29 mg and the total protein 5.6 gm per 100 cc., with an albumin-globulin ratio of 1.8 to 1. The chloride was 96 milliequiv per liter, the cephalin flocculation ++, and the blood phosphorus 2.7 mg per 100 cc. A gastric analysis done after an Ewald meal on October 6 revealed no free acid with a total acidity of 10 units. Gastric analysis after an Ewald meal on November 16 disclosed no free hydrochloric acid, with a total acidity of 2 units. Gastric analysis carried out on November 16 after histamine revealed no free hydrochloric acid throughout, and no acidity was found. (The test was carried out for 75 minutes.) Proctoscopic and barium-enema examinations were negative.

A roentgenogram of the upper gastrointestinal tract showed a gastric ulcer measuring about 1 cm in diameter projecting from the lesser-curvature side of the stomach at the junction of the cardia and body. There was an hour-glass appearance below this. The rest of the upper gastrointestinal study was negative.

In view of the patient's age, clinical history, roentgenologic findings, achlorhydria and poor relief under medical management, a preoperative diagnosis of cancer of the stomach was made, and he was admitted to the New England Deaconess Hospital on November 15.

During his hospital stay a gastric resection was carried out. At operation an ulcer of the lesser curvature of the stomach at the junction of the upper and middle thirds was found surrounded by multiple adhesions. It was impossible to tell whether this was benign or malignant grossly. The operation consisted of partial gastric resection and an end-to-side retrocolic gastrojejunostomy done by the Hofmeister technique.

Microscopical examination on multiple sections (at least 30) of the specimens revealed no evidence of any malignant degeneration, and a diagnosis of benign ulcer of the stomach was made. (Thirteen lymph nodes were also examined and found to be normal.)

Postoperatively, the course was complicated by upper abdominal pain, vomiting and pain in the chest. The medical consultant thought that the patient also had arteriosclerotic heart disease, chronic pulmonary emphysema, chronic bronchitis and malnutrition. Digitalis was given, and potassium iodide administered intravenously, and under this therapy he rapidly improved. He was discharged from the hospital on December 11 improved, on a bland diet, five small feedings a day, accessory vitamins and proper rest.

He was subsequently seen on January 11, 1949, when he weighed 88½ pounds and still complained of some pain in the epigastrium after meals and some diarrhea. A recent letter from him informs us that he has no pain now and is gaining weight.

CASE 2. A 64-year-old married coppersmith was first seen at the Lahey Clinic on January 28, 1944. He complained of epigastric pain of 1 year's duration occurring about 1 hour after meals and awakening him at 1 or 2 a.m. The pain was relieved by alkali and cream. He also complained of the feeling of a lump in the right upper abdominal quadrant and of chronic constipation over a period of years requiring frequent cathartics. The epigastric pain was periodic, leaving him for weeks or more with complete freedom. A roentgenogram of the upper gastrointestinal tract elsewhere had disclosed an ulcer.

A review of the system, and the past and family histories were noncontributory.

On physical examination the patient weighed 138 pounds. Examination of the abdomen revealed tenderness with some muscle guarding on the right side. The right lobe of the prostate was slightly enlarged. The remainder of the physical examination was within normal limits.

The blood pressure was 110/60, and the pulse, respiration and temperature were normal.

Examination of the blood at this time revealed a red-cell count of 4,820,000, with a hemoglobin of 15.1 gm (97 per cent), and a white-cell count of 5500. The blood Hinton reaction was negative. Gastric analysis revealed 60 per cent food content, no free hydrochloric acid, a total acid of 8 units and no occult blood. Examination of the urine showed slight albuminuria, no sugar, a specific gravity of 1.030, an acid reaction and no formed elements.

Roentgenograms of the large intestine and gall bladder were completely normal. A roentgenogram of the upper gastrointestinal tract revealed a normal esophagus but high on the lesser curvature of the stomach was a 1.5-cm out-pocketing, with some thickening and distortion of the rugal pattern of the fundus. This was interpreted clinically as a gastric ulcer, probably malignant because of achlorhydria.

In view of this the patient was admitted to the New England Baptist Hospital on February 7. An exploratory laparotomy was performed, and he was found to have a benign gastric ulcer. Biopsy specimens of the ulcer and the lymph nodes around the omentum were normal microscopically. Postoperatively atelectasis of the left lower lobe of the lung developed, with associated pneumonitis. He recovered from this and was discharged from the hospital on February 25. During his hospital stay he had been managed on a strict ulcer type of dietary management, rest, antacids and antispasmodics.

After this hospitalization he was seen periodically. In April a gastric analysis after an Ewald meal still revealed no free hydrochloric acid, with a total acid of 11 units. Examinations of the blood and urine were negative. Roentgenograms of the upper gastrointestinal tract at that time showed that the gastric ulcer measured only 1 cm in its greatest extent.

The patient was also seen in July, when a free hydrochloric acid of 2 units was found, with a total acid of 8 units on gastric analysis. The blood was normal and a repeat gastrointestinal series at this time revealed that the ulcer had completely healed.

In January, 1945, a gastric analysis demonstrated no free hydrochloric acid and a total acid of 8 units. The blood was normal, and a roentgenogram of the upper gastrointestinal tract revealed no abnormalities.

He was seen again in September, 1947, complaining of a recurrence of epigastric distress, and again physical examination was negative. The blood pressure was 120/80. At this time gastric analysis showed no free hydrochloric acid and a total acid of 8 units. The blood was normal, and examination of the urine negative. A roentgenogram of the upper gastrointestinal tract revealed prepyloric and antral spasm but was otherwise normal.

The patient returned to the clinic in October when a histamine gastric analysis was carried out. A specimen was taken 15 minutes, 30 minutes, 45 minutes, 1 hour and 1½ hours after histamine. The test revealed no free hydrochloric acid with a total acid of 6, 8, 4, 10 and 12 units, respectively. Roentgenograms of the stomach disclosed narrowing of the antrum of the stomach but were otherwise normal. Examination of the blood at this time was normal.

The patient was again seen in December, when a gastric analysis demonstrated no free hydrochloric acid and a total acid of 15 units. The blood was normal and a roentgenogram of the upper gastrointestinal tract revealed no abnormalities.

In January, 1948, gastric analysis demonstrated no free hydrochloric acid and a total acid of 5 units. The blood was normal. In March the blood was still normal. Roentgenograms of the upper gastrointestinal tract revealed recurrence of an ulcer on the lesser curvature of the stomach, with a possible filling defect at the base of the ulcer. The patient was therefore readmitted to the New England Baptist Hospital on April 18 and a high subtotal gastric resection was carried out. In view of the fact that past history included achlorhydria, the specimen was examined with extreme care microscopically, but no evidence of cancer was found and therefore the presence of a benign gastric ulcer with a chronic gastritis was confirmed. Lymph nodes taken from the region at operation were also negative for malignant change. He was discharged from the hospital on May 4, after an uneventful postoperative course, although a further diagnosis of Paget's disease of the pelvis was made at this time.

The patient was readmitted to the hospital on May 18 because of vomiting and lack of appetite. Levine-tube drain-

age of the stomach was instituted for 24 hours, after which he had again responded well and was discharged on May 27.

In October he returned for examination. He had done well except for fainting spells, which the neurosurgical consultant thought were probably on the basis of cerebrovascular disease, but he had had no further gastrointestinal complaints. The blood was normal and a gastric analysis revealed no free hydrochloric acid and a total acid of 20 units. A barium meal demonstrated a normally functioning, subtotally resected stomach and gastroenterostomy.

DISCUSSION

If we take shelter in the definition of peptic ulcer that automatically excludes any benign ulcer with an accompanying achlorhydria, further discussion is unnecessary. However, if we admit the possibility that peptic ulcers may occur under these circumstances it adds one more item to the general problem of peptic ulcer. We consider the 2 cases reported to be clinically indistinguishable from benign "peptic ulcers," and yet we have fairly well proved the existence of an achlorhydria in both. We have also excluded as far as possible any specific etiology for the gastric ulcers. It is interesting to note that in both cases parietal and chief cells were found in the gastric mucosa microscopically.

SUMMARY

Reports concerning the pros and cons of ulcer and achlorhydria are briefly enumerated.

Two cases of benign active gastric ulcers in the presence of persistent achlorhydria are reported.

Pathological confirmation was obtained through the kindness of Dr. William A. Meissner, of the Department of Pathology, New England Deaconess Hospital.

THE EFFECTS OF A SINGLE DOSE OF 2000 UNITS OF PROTAMINE ZINC INSULIN TAKEN BY A DIABETIC PATIENT WITH SUICIDAL INTENT*

ALFRED VOGL, M.D.,† AND SOL H. YOUNGWIRTH, M.D.‡

NEW YORK CITY

THE effects of exceedingly large doses of protamine zinc insulin are known chiefly from patients who have taken excessive amounts by error.¹ The literature, however, also lists 2 cases in which huge quantities were taken with suicidal intent, 490 units in the first case and "one bottle" in the other.² These observations indicate that overdosage with protamine zinc insulin is characterized by a definite sequence of symptoms.

Since the effect of protamine zinc insulin on the blood sugar level develops much more slowly than that of unmodified insulin, there is a considerable initial period during which the compensatory mechanisms (chiefly increased liberation of epinephrine) are able to maintain a more or less adequate blood sugar level by mobilizing the available glycogen in the liver.¹⁻³ However, once the glycogen stores are exhausted, the production of epinephrine is no longer of any avail, and, with the further uptake of insulin from the protamine zinc depot, hypoglycemia becomes clinically manifest and

progressively more severe. If the hypoglycemic state is treated at this point with oral or parenteral administration of carbohydrate the blood sugar level may be raised to normal or close to normal levels, but this effect is very transient. The continuous liberation of insulin in the absence of glycogen stores in the body necessarily leads to recurrent hypoglycemia soon after each therapeutic administration of sugar until the protamine-zinc-insulin depot has been depleted.¹

Without adequate treatment, therefore, the hypoglycemia following overdosage with protamine zinc insulin is characterized by its intractability, severity and duration, and it is apt to lead to irreversible tissue changes (particularly in the brain⁴ and myocardium⁵) comparable to those found in prolonged anoxia.

Coma and vomiting have been a more prominent feature of the hypoglycemia due to protamine zinc insulin than of that caused by regular insulin.¹

A male diabetic patient who took 2000 units of protamine zinc insulin in a single dose afforded us the opportunity of observing some of the effects of such a large dose of insulin on the carbohydrate metabolism.

*From the Third Medical (New York University College of Medicine) Division of Bellevue Hospital.

†Assistant professor of clinical medicine, New York University College of Medicine, associate visiting physician, Bellevue Hospital.

‡Assistant resident in medicine, Bellevue Hospital.

CASE REPORT

The patient was a 63-year-old man who had had diabetes for about 10 years and who required 40 units of protamine zinc insulin daily. For the preceding few years he had also been treated for arteriosclerotic heart disease with anginal syndrome. For many years he had been unable to work because of poor vision. He became depressed, and 1 year previously he had attempted suicide with insulin.

On the morning of November 2, 1948, the patient received his usual injection of 40 units of protamine zinc insulin. At approximately 5 p.m. on the same day, the patient announced to his wife that he had a little while previously injected into himself the contents of "three bottles" of protamine zinc insulin with the intention of killing himself. The wife found the three empty bottles, two of 80 and one of 40 units per cubic centimeter (representing a total of 2000 units), the contents of which the patient claimed to have injected subcutaneously. At this time he showed no unusual symptoms. A doctor who was called at once declared treatment unnecessary.

During the night the patient had a few episodes of perspiration and apprehension, not different from the hypoglycemic symptoms occasionally experienced in the past. His wife treated them successfully with fruit juice and frequent feeding.

On the following morning he was taken to a hospital, where no sign of insulin reaction was found and, after several hours, he was transferred to the psychiatric division of Bellevue Hospital because of his repeated suicidal attempts. Immediately prior to his transfer he became apprehensive and started to perspire. He was given 40 cc. of 50 per cent glucose solution intravenously, and drank a cup of orange juice, immediate improvement followed.

On admission to Bellevue Hospital at 5 p.m. on November 3 he was fully conscious and oriented and asked for something to eat. He was sweating moderately and appeared very apprehensive but in no acute distress. The skin was cool, and the pulse very rapid and irregular. He was immediately given 50 cc. of 50 per cent glucose intravenously. Sweating and apprehension disappeared promptly, the pulse rate slowed, and he appeared comfortable and spoke rationally. Physical examination at this time showed a temperature of 98.4°F, a pulse of 64 and respirations of 16. The blood pressure was 130/68. Fundoscopy revealed diabetic retinopathy. The heart was enlarged. The chest was clear. The abdomen was soft. On both thighs were many injection marks. Neurologic examination was negative. The urine on admission was free of sugar and acetone.

The patient's course in the hospital was characterized by great difficulty in attaining and the inability to maintain a normal blood sugar level. This persisted for 6 days in spite of almost continuous oral and parenteral administration of huge amounts of carbohydrates. During this period there was a persistent tendency to lapse into hypoglycemia whenever the therapeutic efforts were relaxed.

Until 7 a.m. of the 2nd day—that is, during the first 38 hours after the insulin had been taken, the symptoms were mild and relatively easily controlled. This period included the first 14 hours at Bellevue Hospital, when 320 gm of carbohydrates was given—295 gm by mouth and 25 gm by vein.

After this 38-hour period had passed, however, the patient started to vomit and rapidly went into coma. At this time the blood sugar was less than 10 mg per 100 cc., 50 cc. of 50 per cent glucose was at once given intravenously and followed by an intravenous infusion of 12.5 per cent glucose in water. About 2 hours later the patient regained consciousness and was able to take food by mouth. He remained comfortable, except for a few episodes of sweating although the blood sugar did not rise above 33 mg per 100 cc. that afternoon.

The blood sugar was still 54 mg per 100 cc. at 10 p.m. on the 3rd day. During the 15-hour period from the onset of coma at 9 a.m. until midnight he received a total of 275 gm of glucose intravenously and 300 gm of carbohydrates orally in the form of sweetened fruit juices.

His condition became critical during the night and the following morning, when hypoglycemia was most profound and the largest amounts of carbohydrate he was to receive on any day were required. The intravenous infusion of

glucose had inadvertently been stopped, probably for about 1 hour before 2 a.m. At this time he was found vomiting and perspiring and rapidly lapsed into coma. After 50 cc. of 50 per cent glucose had been given intravenously he recovered quickly. The infusion was restarted at the same time. At 7:30 a.m. the infusion was stopped again. About 1 hour later the patient began to vomit, became deeply comatose, had a rapid, irregular pulse and developed pulmonary edema. The blood pressure was 180/80. He was again given 50 cc. of 50 per cent glucose intravenously but this time without response. The blood sugar of a specimen drawn a few minutes after the intravenous injection of glucose was reported as less than 10 mg per 100 cc. The serum potassium was 3.5 milliequiv per liter at this time. In view of the pulmonary edema it was believed that infusions should not be continued for the time being, and glucose was given in the form of a 50 per cent solution, 50 cc. at a time for a total of 260 gm between 9 a.m. and 9 p.m. In addition, 1800 cc. of milk and egg nog, containing 150 gm of carbohydrates, was fed to the patient through a Levine tube. He was rapidly digitalized and given a transfusion of 500 cc. of blood. After 4 hours of treatment, his coma lightened, but he remained confused and drowsy for the rest of the day. Pulmonary edema cleared gradually. During this period of generous oral and parenteral administration of glucose the urine remained almost consistently sugar free, and the blood sugar was 35 mg per 100 cc. at 12:40 p.m.

After 6 p.m. on the 4th day tube feeding was discontinued because of abdominal distention. Five hundred cubic centimeters of whole blood was given slowly. By 9 p.m. it was considered safe to resume glucose infusions, a 22 per cent solution was used for this purpose, and it was supplemented on two occasions by 50 cc. of 50 per cent solution injected intravenously. By midnight the urine showed a ++ test for sugar.

The patient had received a total of 920 gm of carbohydrate (680 gm by vein and 240 gm orally) during the preceding 24 hours. But shortly after midnight the urine was again sugar free, and restlessness and perspiration reappeared.

On the next morning he experienced mild hypoglycemic symptoms. At 8 a.m. the blood sugar was 50 mg per 100 cc. The 22 per cent intravenous glucose drip and the Levine-tube feedings were continued until 4 p.m., when the urine samples contained increasing amounts of sugar.

On the 5th day the patient's sensorium appeared clear, and he was able to take food and was started on a diet containing 180 gm of carbohydrate. His urine remained sugar free the rest of the day.

On the 6th day the patient again appeared drowsy most of the time. The blood sugar was found to be 30 mg per 100 cc. at 9 a.m., even though he had been receiving carbohydrate feedings during the night. During the day his condition remained unchanged and the urine was free of sugar on a diet containing 260 gm of carbohydrate.

He was, therefore, again started on intravenous 22 per cent glucose at 6 p.m. on the following day. Soon afterward he was found to be excreting increasing amounts of sugar (a +++ to ++++ test) in the urine. The infusion was stopped at 6 a.m. At 10 a.m. the blood sugar was 210 mg per 100 cc.

From the 8th day on, the patient was well oriented and took his full diet containing 180 gm of carbohydrate. During this period the urinary sugar varied from 0 to ++++, and the blood sugar remained around 200 mg per 100 cc.

On the 15th day it was decided to start the patient on insulin again, he received repeated small doses of regular insulin and was gradually returned to protamine zinc insulin.

Two weeks later the diabetes was well controlled on 40 units of protamine zinc insulin. The patient's physical and mental condition was quite satisfactory by this time, he was completely oriented and according to the statement of his wife had not changed in any way.

An electrocardiogram taken during the coma and pulmonary edema on the 3rd day showed sinus tachycardia (a rate of 144 per minute), with occasional premature ventricular contractions and elevated ST segments in Lead 2 and 3. Twelve days later, when the procedure was repeated, the rhythm was regular and the ST segments isoelectric.

In summary, after a single hypodermic injection of 2000 units of protamine zinc insulin this diabetic patient showed severe manifestations of hypoglycemia for 6 consecutive days with the greatest severity on the 3rd day. In this period he received almost 3000 gm of carbohydrate (1425 gm by

vein and about 1400 gm by mouth), but the urine remained sugar free most of the time and the blood sugar never exceeded 54 mg per 100 cc. Twelve days elapsed before it became necessary to reinstitute insulin therapy, although he had previously required daily injections of 40 units.

DISCUSSION

This case illustrates the problems created by an unusually great overdosage of protamine zinc insulin. The initial absence or paucity of symptoms in no way minimizes the seriousness of the situation. When a person is known to have received or is suspected of having received an excessive amount of protamine zinc insulin, he must be regarded as an emergency^{1, 7, 8} and kept under careful observation lest severe hypoglycemia develop abruptly and become increasingly difficult to control, if not fatal.

The experience with this patient also showed that prompt improvement of symptoms after carbohydrate administration must not give rise to a false sense of security. The response to the administration of glucose in such a case is bound to be quite transient since the liberation of insulin from the injected depot takes place over a long period, whereas the glycogen stores in the body are depleted during the early phases of hyperinsulinism. It is therefore of prime importance to administer a continuous supply of readily available carbohydrate to such patients.⁷ Oral feedings can be depended upon only if the patient remains fully conscious, a nurse is in constant attendance, and the patient does not vomit. If the patient is unconscious, full reliance cannot be placed on feeding through a Levine tube since gastric atony with retention may occur in this state.¹ Continuous intravenous drip infusion is therefore preferable during the critical phase. The attempt to give a sufficient amount of carbohydrate by this means is, of course, always fraught with the danger of flooding the circulation to a degree at which pulmonary edema results, as occurred in the case reported above. This difficulty can probably best be overcome by the use of a highly concentrated solution. A 22 per cent solution of glucose in water, occasionally supplemented by the further intravenous injection of 50 cc of a 50 per cent solution, was finally resorted to.

It should be emphasized that on the third day, during the most profound phase of hypoglycemia, a brief interruption of the parenteral supply of glucose led to a virtually complete disappearance of sugar from the circulating blood and to deep coma from which recovery was relatively slow. From the experiences in cases reported in the literature it may be assumed that serious organic damage would have resulted if such a degree of hypoglycemia had been allowed to persist longer.^{2, 4, 9, 10} Conversely, the patient's recovery without any demonstrable cerebral or cardiac damage may be attributed to the almost continuous maintenance of the blood sugar above levels injurious to brain

and heart by means of intravenous infusions and frequent feedings and by the intravenous administration of additional concentrated solutions of glucose whenever, in spite of all efforts, the blood sugar dropped below critical values. The recovery is the more remarkable since the patient had signs of pre-existent generalized arteriosclerosis with symptoms of circulatory (and particularly coronary) insufficiency. Other patients have been known^{4, 11, 12} to develop permanent brain damage of varying occasionally extreme severity after prolonged hypoglycemia, even though it resulted from far smaller doses of insulin.

It is generally recognized that the action of individual therapeutic doses of protamine zinc insulin may extend well beyond a twenty-four-hour period, even into the third day.⁸ In fasting patients single injections have maintained hypoglycemic levels for as long as forty-eight to seventy-two hours.¹¹ In animal experiments, a single injection of protamine zinc insulin has produced hypoglycemia of thirty hours' duration in rats and of three to five days' duration in dogs.¹⁵ The larger the dose given, the more prolonged the effect. The same statement, incidentally, holds for unmodified insulin, with which the duration as well as the intensity of the effect also varies in proportion to the size of the dose given.^{16, 17} To our knowledge, hypoglycemia of six days' duration, as reported above, has not been noted after a single injection of insulin. However, there is no basis for comparison, since there is no case on record in which such a large quantity of insulin was received in a single dose. The knowledge that the amount of insulin will directly determine the duration of its effect assumes practical importance whenever a large dose of protamine zinc insulin is given either in error or by design. Any prediction about the course of events in such cases, particularly regarding the duration of the critical period and the length of time during which continuous, vigorous therapy will be required, obviously cannot be based on experience with the customary doses of insulin, but must be estimated according to the amount administered. Periods of hypoglycemia of sixty hours, as observed by Aitkin,¹⁸ after 100 units of protamine zinc insulin, and of one hundred and forty-four hours, as seen in our case after 2000 units of protamine zinc insulin, could serve as two indexes that may be useful for calculation in cases of this kind.

The question may be raised why the patient received a transfusion of whole blood on the third day of treatment. The indication was based on Joslin's⁷ opinion that a transfusion of fresh blood may be able to supply the respiratory enzymes, which appear to be inhibited during hypoglycemia.¹⁹ It may also assist in the restoration of a disturbed electrolyte balance.

The electrocardiographic findings are noteworthy. During the episode of greatest hypoglycemia with coma and pulmonary edema, the findings included a sinus tachycardia (a rate of 144 per minute), premature ventricular contractions and definite elevation of the ST segments in Lead 2 and 3. At this time the blood potassium level was normal.^{20, 21} Twelve days later the ventricular rate was 64 per minute, and the ST segments isoelectric. These changes are at variance with those observed by others during hypoglycemia.^{22, 24}

SUMMARY

A case in which suicide was attempted with a single injection of protamine zinc insulin is reported. The patient had few symptoms during the first twenty-four hours but, in spite of vigorous and continuous treatment, developed increasingly severe hypoglycemia, with periods of coma on the second and third days, and recurrent manifestations of milder hypoglycemia, with a blood sugar of 30 mg per 100 cc up to the sixth day. During this period he received close to 3000 gm of carbohydrate and yet was unable to maintain or even approach a normal blood sugar level. The blood sugar, however, was kept above critical values (at 30 to 50 mg per 100 cc) most of the time, and the patient suffered no demonstrable permanent damage.

The possible causes for the delayed appearance of symptoms, the severity of the hypoglycemia and the difficulty in maintaining an adequate blood sugar level after an excessive dose of protamine zinc insulin are discussed. It is stressed that the duration of the hypoglycemic effect increases in proportion to the size of the dose. This fact may account for the extremely protracted course of hypoglycemia in the case reported, exceeding that in any other known case on record.

The therapeutic urgency in this type of case is emphasized, in particular, the necessity of continuous and prolonged intravenous administration of carbohydrate.

The indication was based on Joslin's⁷ opinion that a transfusion of fresh blood may be able to supply the respiratory enzymes, which appear to be inhibited during hypoglycemia.¹⁹ It may also assist in the restoration of a disturbed electrolyte balance.

abdomen and buttocks. In desperation and not knowing where else to inject her insulin, she inquired about the possible harm that might come from injecting insulin into the lipoatrophic areas. There did not appear to be any serious objection to reinjection of these depressed areas. The patient

and has practically recovered from all her deformities.

We have since advised 6 other patients suffering from insulin lipoatrophy to inject their daily insulin doses repeatedly into the deepest portion of the depression and in all these cases have seen, in one

returned one month later, and it was surprising to find that one atrophic area which the patient had not injected for two years, had, after repeated daily injections, filled out and returned to its normal configuration.

As a result of this experience, the patient has since reinjected all the scooped out depressions

month's time, striking complete recovery from the deformities.

SUMMARY

A method for the successful treatment of insulin lipoatrophy is briefly presented.

LIPOATROPHY FOLLOWING THE INJECTION OF INSULIN*

A Method of Control

WILLIAM S. COLLENS, M.D.,† LOUIS C. BOAS, M.D.,‡ JAMES D. ZILINSKY, M.D.,‡ AND
JEROME J. GREENWALD, M.D.‡

BROOKLYN, NEW YORK

AMONG the many problems that have arisen since insulin was introduced as an agent in the treatment of diabetes mellitus is one concerned with the development of local fat atrophy at the site of insulin injections. Although of relatively infrequent occurrence, the problem has always proved to be very distressing to the patient because of the considerable amount of disfigurement it produces.

Insulin lipoatrophy is a condition in which the subcutaneous fat disappears at the site of the insulin injection, leaving a depression in the skin (Fig

considered responsible are the cresols used as a preservative of insulin, alcohol and its denaturants used in sterilizing syringes and needles, injury to fat cells following the introduction of the hypodermic needle, possible lipolytic ferments present in insulin and possible nerve injury.

On the basis of the possibility that this condition might be an allergic phenomenon, some of the patients in our clinic were subjected to skin tests by the intradermal injection of various commercial brands of insulin. There was no uniformity in the reaction, some being negative and others mildly

1 and 2). It develops in some cases when the insulin is injected at the same site over a period of as little as four weeks. In other cases it may take months to appear. It may occur after the use of any type of insulin and is unrelated to the dosage and concentration.

The cause of this lipoatrophy is unknown. There has been no satisfactory explanation to account for the complication although several theories have been propounded. Among the possible factors

positive. Such reactions were also obtained in other diabetic patients who revealed no manifestations of lipoatrophy. It was therefore not possible to come to any conclusion regarding the existence of any unusual sensitivity in these cases. Furthermore, there are no experimental or clinical data available to shed any light on the mechanism responsible for the condition.

A successful method for the treatment of lipoatrophy is presented. This method was conceived as the result of a patient's suggestion. A young woman, twenty-three years of age, who had been diabetic since the age of twelve, had developed multiple areas of lipoatrophy on the arms, thighs,

myocardium Quinidine concentrations in various tissues range from two to thirty-nine times the plasma concentration,^{113 114} and the level in auricular and ventricular muscle falls within this range.¹¹³ The time at which the highest quinidine concentration is reached, as well as the subsequent fall in concentration in cardiac muscle and other tissues, is correlated with plasma-level changes.¹¹³ These observations indicate a ready equilibrium between the plasma and tissues of the dog.

Few observations have been made in man of the extent to which quinidine is concentrated in various tissues. In normal persons receiving single and repeated doses of the drug the concentration of the quinidine in the cellular elements of the blood varies from 0 to 80 per cent of the plasma level.⁶⁴

Excretion and metabolic alteration The total urinary excretion of unaltered quinidine amounts to 5 to 20 per cent of the administered dose.^{64 112} Various metabolic products are recovered from urine but account for less than 5 per cent of the quinidine administered.^{112 115} In view of the essentially complete absorption, limited localization and limited excretion, it is apparent that the fate of quinidine in the body is primarily one of metabolic alteration.

Action on the Cardiovascular System in Animals

The main myocardial effects of quinidine are an increase in refractory period, thereby decreasing myocardial excitability, and a decrease in the rate of impulse conduction.^{116 117} Numerous observations have been made^{118 124} of the action of the drug on the cardiovascular system of various animals. Comparison is difficult, however, not only because of species difference but also because of different anesthetics and operative procedures and, above all, different doses of quinidine given intravenously at varying rates.

Recent studies in dogs¹²⁵ have described the cardiovascular changes as plasma quinidine levels are progressively raised by continuous intravenous infusions of the drug. The changes observed are closely correlated with the plasma concentration of quinidine. A fall in arterial blood pressure occurs with low plasma levels. As the concentration rises, sinus slowing appears and progresses and is accompanied by various electrocardiographic manifestations of interference with impulse formation in the sinoauricular node. There is finally a transition to auriculoventricular-node rhythm followed by intraventricular conduction block, ventricular extrasystoles, ventricular tachycardia, ventricular fibrillation and death. These experimental observations cannot be applied directly to man. However, as discussed below, many of these cardiovascular effects seen in the dog may well have clinical counterparts.

Action on the Cardiovascular System in Man

Measurement of cardiac action and its relation to plasma concentration The end of an arrhythmia is an all-or-none phenomenon that cannot be measured, and other indexes must therefore be used to determine the action of quinidine on the heart. Changes in rate or in the electrocardiogram permit determination of the time factors in the action of the drug and, in a few cases, enable the intensity of action to be related to the size of the dose. Pertinent observations have been recorded on

The occurrence and degree of slowing of the auricular oscillations in the electrocardiograms of patients with auricular fibrillation^{64 113 126-128} and auricular flutter.^{7 133 134}

The occurrence and degree of prolongation of the QRS^{125 126} and QT¹²⁷ intervals of the electrocardiogram.

The effect on constant extrasystolic arrhythmias.^{135 139}

The slowing of the rate without restoration of normal sinus rhythm in patients with paroxysmal ventricular tachycardia.^{46 140 141}

The occurrence and degree of increase in the ventricular rate in undigitalized patients with auricular fibrillation.¹²⁶

The slowing of the rate without restoration of normal sinus rhythm in certain patients with paroxysmal auricular tachycardia.¹⁴²

The disappearance of the electrocardiographic abnormalities in the Wolff-Parkinson-White syndrome (short PR interval and wide QRS interval).¹⁴³

The development of bundle-branch block¹⁴⁴ in certain subjects with sinus tachycardia.

These studies following *oral* and *intramuscular* quinidine show that the time of onset of drug action, the time of maximum effect and the duration of action parallel closely changes in plasma concentration of quinidine described above.

Although plasma concentrations following *intravenous* quinidine are not known, the maximum cardiac effect as measured by auricular slowing in patients with auricular fibrillation and auricular flutter⁷ occurs almost immediately after completion of the intravenous injection and certainly within ten minutes. The maximum effect of 0.4 gm intravenously was approximately equivalent to 0.8 gm by mouth. These and other observations¹⁴⁵ indicate that the duration of action after intravenous administration is only a few hours.

It has been suggested^{113 132} that the relation between plasma concentration and cardiac action of quinidine is not strictly quantitative. However, the correlation is good and it seems valid, therefore, to use changes in the plasma concentration as a guide to changes in the intensity of action on the heart.¹⁰⁷

MEDICAL PROGRESS

MEASURES USED IN THE PREVENTION AND TREATMENT OF CARDIAC ARRHYTHMIAS (Concluded)*

ARTHUR J. LINENTHAL, M.D.,† AND A. STONE FREEDBERG, M.D.‡

BOSTON

QUINIDINE (AND OTHER CINCHONA ALKALOIDS)

Quinidine is of recognized value in the prevention and treatment of various cardiac arrhythmias, such as paroxysmal ventricular tachycardia and paroxysmal auricular fibrillation. However, there is considerable disagreement about the exact indications and contraindications, the nature and frequency of toxic reactions, the routes of administration and the dosage schedules of the drug. Since there is so much confusion surrounding the use of quinidine, the pertinent available information has been assembled and is discussed in some detail.

Physiologic Disposition

Knowledge of the fate of quinidine in man has been obtained by sensitive, accurate and specific analytical methods developed in the past few years.⁹⁹⁻¹⁰⁵ The relation between oral dosage and the resulting plasma concentration has been studied, and information obtained on absorption, distribution, excretion and metabolic alteration, which combine to determine the level of quinidine in the blood.

Relation of oral dosage to plasma concentration Within fifteen minutes of a single oral dose of 0.2 to 1.0 gm. of quinidine sulfate the alkaloid can be detected in the plasma. Maximum levels are reached in one to three hours and may be maintained for two or three hours.¹⁰⁷⁻¹⁰⁹ The subsequent fall is at first fairly rapid and then slower. Approximately 50 per cent and 25 per cent of the peak value remain after eight and twelve hours respectively. At the end of twenty-four hours only a trace of quinidine can be demonstrated in the plasma. Average peak plasma concentrations after single doses of 0.2, 0.4, 0.6 and 1.0 gm. are, respectively, 0.8, 1.3, 2.0 and 2.7 mg. per liter.^{61-107, 110}

When the same dose of quinidine sulfate is administered at two-hour intervals—that is, at the time of the peak response to the preceding dose—the plasma concentration increases, but the increase becomes smaller and smaller with each successive dose, and the curve levels off after four or five doses.

§Associate in medicine, Harvard Medical School; visiting physician and associate in medical research, Beth Israel Hospital.

Presumably, at this point, the rate of absorption balances the combined rates of excretion and metabolic alteration.⁶¹⁻¹⁰⁷

When the same dose is repeated at intervals of six, eight or twelve hours, the peak level after several days is not significantly greater than that after the first dose. The maximum concentration is slightly lower when the doses are given every twelve hours than when they are given every six to eight hours, with the more frequent administration the concentration is maintained at a higher level in the period between peaks. When the size of the dose is increased, the height of the peak is raised appreciably.⁶¹⁻¹⁰⁷ The size of the individual dose is the most important factor in obtaining a high plasma level of quinidine.⁶¹ Cumulation is minimized by rapid elimination, and, therefore, the total daily dose and the total weekly dose are of little significance.

Relation of parenteral dosage to plasma concentration Limited information is available regarding the plasma concentration of quinidine following intramuscular administration.⁶¹ Initial absorption is more rapid than after oral administration; the peak level is no higher and does not occur significantly earlier. The rate of disappearance and the time required for complete disappearance from plasma are the same as those after oral administration. As would be expected on the basis of these findings, the plasma concentration following repeated intramuscular doses follows the same pattern as that after repeated oral doses.⁶¹

We are not familiar with any data on the plasma levels of quinidine following intravenous administration of the drug in man.

Absorption Quinidine is practically completely absorbed from the human gastrointestinal tract. After oral administration of repeated doses, less than 5 per cent can be recovered from the stools.¹¹¹⁻¹¹⁷ The rapidity with which the drug can be detected in the blood suggests that absorption must at least begin in the stomach. Absorption also occurs from the intestinal tract as evidenced by studies with enteric-coated tablets of quinidine sulfate, which, presumably, pass through the stomach unchanged. Peak plasma concentrations following the enteric-coated preparation are comparable to those observed after the administration of uncoated tablets.⁶¹

Distribution Distribution studies in dogs have shown no unusual concentration of quinidine in the

be given. Inasmuch as reactions to quinidine may be expected to occur within a few hours after a dose, a longer period of observation is not necessary. The appearance of severe untoward symptoms following the first of a proposed series of doses will serve as indication for modifying the dosage schedule. It is pertinent to emphasize the infrequency of serious reactions to quinidine.

Cardiac toxicity Although the potentially more serious toxicity of quinidine is related to its action on the heart, experience suggests that such toxicity is uncommon. The controversial problem of embolization in patients with chronic auricular fibrillation receiving quinidine will not be discussed here.⁶⁷ As mentioned above, increasing quinidine concentrations in dogs are associated with various manifestations of interference with normal cardiac impulse formation and conduction and, finally, with death. Although in some cases the relation to the drug is not definite, clinical counterparts of these experimental observations have been described in patients with various arrhythmias receiving quinidine. These include sinus arrhythmias,⁶⁷ auricular standstill,¹⁷⁴ auriculoventricular block,¹²⁶ bundle-branch block,¹⁴⁴ ventricular extrasystoles,⁵⁴ ¹²⁶ ¹⁶² ¹⁷⁶ ¹⁷⁷ ventricular tachycardia,⁵⁴ ⁶⁶ ¹²⁶ ¹⁶² ¹⁷⁶ transient ventricular fibrillation¹⁷⁸⁻¹⁸¹ and death.⁷ ⁵⁴ ¹⁸² ¹⁸³ In most cases these phenomena have been observed with moderate or large doses of quinidine. However, sufficient information is not available to indicate the likelihood of producing an untoward cardiac reaction in a given patient with a particular dose or plasma level of quinidine.

When quinidine is being administered, particularly in large doses, it is important to have some guide that will warn of approaching cardiac toxicity. It has been suggested that QRS lengthening of more than 25 per cent of the control value is not safe,¹³⁶ but more marked prolongation of the QRS complex has been witnessed without untoward effect when the situation required larger amounts of the drug.¹⁸⁴ When quinidine administration is associated with auricular standstill, bundle-branch block, a rise in ventricular rate, ventricular extrasystoles, ventricular tachycardia or transient ventricular fibrillation the drug should be stopped. Frequent electrocardiograms are thus helpful in controlling the therapeutic administration of quinidine, and correlation of electrocardiographic changes and plasma concentrations now being carried out¹⁸⁵ should give information of considerable value.

Contraindications

The only absolute contraindication to the administration of quinidine is a history of serious reaction to the drug.

Relative contraindications frequently mentioned include long-standing auricular fibrillation, bundle-branch block, auriculoventricular block, severe cardiac failure, marked cardiac enlargement, long-

standing valvular disease, subacute bacterial endocarditis, various acute infections and advanced age of the patient. The evidence that these factors increase the likelihood of cardiac toxicity is not conclusive, and they should not prevent use of the drug when there is a definite indication. Acute myocardial infarction has been considered both an indication and a contraindication. In such cases clinical experience with prophylactic doses of 0.2 to 0.3 gm of quinidine sulfate three or four times a day has not revealed any unusual incidence of toxic reactions.

Indications

Quinidine may be used effectively in the prevention and treatment of paroxysmal auricular fibrillation, paroxysmal auricular flutter, paroxysmal supraventricular tachycardia, paroxysmal ventricular tachycardia and ventricular extrasystoles. It has also been found to be of value in the treatment of certain cases of chronic auricular fibrillation when the arrhythmia may be causing recurrent embolization¹⁸⁶ or cardiac failure.¹⁸⁷

Quinidine is generally recognized as the drug of choice in paroxysmal ventricular tachycardia. In most other arrhythmias, however, other agents (Table 1) may be effective, and the relative value of quinidine cannot be accurately determined on the basis of the available evidence.

Preparations and Routes of Administration

Since it is promptly and almost completely absorbed from the gastrointestinal tract, quinidine is generally administered by mouth. Quinidine sulfate (*USP*) is available in 0.2-gm and 0.3-gm tablets for oral use.

Parenteral administration may be necessary when an acute arrhythmia is associated with collapse, unconsciousness, vomiting or other factors that make oral use impossible or absorption from the gastrointestinal tract uncertain. Injectable quinidine preparations are not readily available but may easily be prepared as stable aqueous solutions that can be stored in ampoules for emergency use. A 15 per cent solution of quinidine hydrochloride dissolved with the addition of 15 per cent antipyrine and 20 per cent urea¹⁸⁶ and a 15 per cent solution of quinidine lactate¹⁸⁸ have been used in man — the first intramuscularly, and the second both intramuscularly and intravenously. Quinidine acts more quickly intramuscularly than by the oral route, is at least as effective and may cause even fewer side reactions.¹⁸⁶ Quinidine has been used intravenously for therapeutic purposes,²⁵ ¹⁸⁹ ¹⁹³ but the advantage of the greatly increased speed of action is rarely important enough to warrant the greater danger of serious toxicity. The intramuscular route is the one of choice for parenteral administration.

Little information is available, as yet, on the relation between the plasma concentration of quinidine and the prevention or treatment of various arrhythmias. In 2 patients¹¹⁰ with recurrent auriculoventricular-node tachycardia, attacks were absent at plasma quinidine concentrations above 10 mg per liter but recurred when the levels were lower. The dose required to maintain this "critical" level was at least 0.2 gm of quinidine sulfate every four hours. In a small number of patients with various arrhythmias, restoration of normal sinus rhythm has occurred at levels ranging from 2 to 10 mg per liter.¹¹⁶

Comparison of the cardiac action of quinidine and other cinchona alkaloids. The action of quinidine from natural sources has been compared with that of other natural and synthetic cinchona alkaloids.^{126 128 130 137 147-149}

These various studies indicate that, with equal doses, natural and synthetic quinidine show the same activity and dihydroquinidine is more active, cinchonidine, cinchonine and quinine are less active. Inasmuch as quinine is occasionally used instead of quinidine in the treatment of cardiac arrhythmias, it is of practical importance to appreciate the quantitative difference in the action of the two drugs. In addition to the greater activity of quinidine on the basis of equal doses, it has been found that the maximum effect on the rate of the auricular oscillations in auricular fibrillation obtainable with increasing doses of quinine is never as great as that obtainable with increasing doses of quinidine.¹⁴⁷ Accordingly, the two drugs are not completely interchangeable. However, quinine has been used effectively in the treatment of paroxysmal auricular tachycardia,^{150 151} paroxysmal auricular fibrillation,¹⁵¹ paroxysmal auricular flutter¹⁵¹ and paroxysmal ventricular tachycardia.⁴⁶

Other cardiovascular effects. Various other cardiovascular effects of quinidine have been measured both in normal persons^{137 152} and in patients with cardiac disease,^{152 153} but the results are conflicting. After large single doses of quinidine sulfate by mouth, the heart rate has been found to show no significant changes^{137 152} or an increase¹⁵³, arterial blood pressure has been observed to fall¹⁵⁰ or to remain unchanged¹⁵³, cardiac output has shown no change in normal persons,¹⁵² a decrease or no change in cardiac patients without congestive failure¹⁵² and a rise from a previously low value in patients with cardiac decompensation.¹⁵² These last patients also showed a fall in arterial pressure and drop in a previously elevated right ventricular pressure. A fall in arterial pressure and a drop in peripheral resistance without change in cardiac output has been attributed to an action of quinidine on the peripheral vascular bed.¹⁵² The reported efficacy of quinidine in the treatment of angina pectoris^{154 155} suggests that the drug also causes dilatation of the coronary arteries.

Toxicity

Uncertainty about the toxicity of quinidine undoubtedly contributes to its limited use by many physicians. Although many questions regarding quinidine toxicity cannot be answered without further study, our experience and that of other clinicians indicate that serious side reactions are rare.^{127 128 137}

Quinidine, like quinine, has been labeled "a general protoplasmic poison."⁷⁶ The term is meaningless, however, and the toxicity of these substances for vertebrates is low.¹⁵⁸

*Cinchonism and other reactions.** In man, the most frequent side reactions are grouped under the term "cinchonism," the nature and severity of the symptoms varying, in general, with the size of the dose. In its mild form, this syndrome is not uncommon and includes nausea, abdominal discomfort, diarrhea, ringing in the ears and dizziness. If administration is interrupted, the symptoms usually subside promptly. On readministration, especially if the dose is increased more slowly,^{54 159} larger amounts may be given and higher plasma levels reached in the same patient without recurrence of symptoms. The little information available⁶⁴ suggests a lack of correlation between plasma concentration and the early symptoms of cinchonism. From 2.0 to 3.0 gm of quinidine sulfate has been administered repeatedly by mouth with the development of only minor side effects.^{160 161}

Certain persons may develop mild cinchonism even after a small oral dose of 0.2 gm. This mild, not uncommon but unimportant reaction may be inconstant in the same subject on different occasions and is no contraindication to further administration of quinidine.

Rarely, syncope,¹⁵⁹ convulsions,¹⁵⁹ sudden collapse¹⁶² and respiratory difficulty^{153 164} have been observed after a single small dose of quinidine. The evidence relating these phenomena to the administered quinidine is, however, inconclusive.

Reactions of an "allergic" nature have been described with quinidine but are rare. Skin rashes have been reported,^{137 165} but the best documented case reports concern the occurrence of fever¹⁶⁶ and thrombocytopenic purpura.¹⁶⁷ In each case the sensitivity has been an *acquired one, developing after one to three weeks of drug administration*. After the subsidence of the initial episode, readministration of a single small dose of quinidine has been followed by reappearance of the phenomena within two hours. In such cases quinine may be of value instead of quinidine, since persons sensitive to one are generally not sensitive to the other.^{166 168 172}

It has usually been recommended that, to detect sensitive persons, a small "test dose" of quinidine

*We have purposely avoided the term 'idiosyncrasy'. The literature on quinidine is needlessly confused by its use. *Webster's New International Dictionary of the English Language* defines 'idiosyncrasy' as 'a characteristic distinguishing an individual' and it may therefore properly be applied to many of these reactions.

prophylactic purposes, in patients whose repeated paroxysms of tachycardia have not been prevented by medical measures

Digitalis Glycosides

The main indication for the use of cardiac glycosides is congestive heart failure regardless of the rhythm. Digitalis preparations are widely used in patients with paroxysmal supraventricular tachycardia, auricular fibrillation and auricular flutter particularly if heart disease is present and the paroxysmal nature of the tachycardia is not clear. The mechanism of action of digitalis in preventing and stopping auricular arrhythmias is obscure. It is important to remember that paroxysmal tachycardia of ventricular origin is considered by many to represent a contraindication to digitalis therapy.

Choice of preparation The various considerations governing the selection of a digitalis glycoside have been the subject of a recent report.¹⁹¹ Numerous digitalis preparations have been used intravenously in the treatment of acute supraventricular arrhythmias. Although a great deal of emphasis has been placed on lanatoside C intravenously,^{59, 195, 196} there is no clear evidence that it accomplishes more than other digitalis preparations such as Digalen,⁵⁹ Digifolin⁶⁷ and ouabain.¹⁹⁷ Oral preparations have been used to prevent the recurrence of these arrhythmias.¹⁹⁵

Side effects The evidences of digitalis overdosage are well known. In the various studies with intravenous lanatoside C mentioned above, only occasional nausea and rare transient ventricular extrasystoles have been observed.

Efficacy in treatment of paroxysmal supraventricular arrhythmias Rapid restoration of normal rhythm has been observed after half to full "digitalizing" doses of cardiac glycosides intravenously in patients with paroxysmal auricular tachycardia, paroxysmal auricular fibrillation and paroxysmal auricular flutter. In many cases the effect occurred within five to ten minutes of the injection. In others, the change in rhythm occurred after a longer interval, up to twenty-four hours, and the relation to the drug was therefore not definite. In some cases ventricular slowing may be noted, although normal sinus rhythm is not restored. This may result in symptomatic improvement, and unless electrocardiograms are taken sinus rhythm may be thought to have returned.

In several cases of paroxysmal auricular tachycardia, Weisberger and Feil⁵⁹ found that carotid-sinus pressure, although previously ineffective stopped the attack immediately when applied after the administration of lanatoside C. This is in accord with the observation that digitalis increases the sensitivity of the carotid-sinus reflex.^{40, 60} A similar effect has been seen, as pointed out above in the first section after acetyl-beta-methyl-choline and neostigmine.

Efficacy in preventing paroxysmal supraventricular arrhythmias Tandowski¹⁹⁸ has maintained digitalization with 0.5 to 1.0 mg of lanatoside C by mouth daily in 8 patients with paroxysmal auricular flutter and auricular tachycardia. Only three attacks occurred during a fifteen-month period of treatment compared to twenty-four during a twelve-month period prior to digitalization. Although the observations were not completed by the omission of digitalis to determine if the frequency of attacks increased the results are consistent with our own experience.

Summary Digitalis preparations are of value in the prevention and treatment of paroxysmal supraventricular arrhythmias. The intravenous route of administration has been found particularly useful in stopping paroxysms of tachycardia. These substances can be given safely in therapeutic doses and may, of course, be of value for associated cardiac failure.

Magnesium Sulfate

High concentrations of magnesium ion depress the cardiac conduction system and heart muscle. As the serum concentration of magnesium ion is increased in animals, prolongation of the PR and QRS intervals is observed, the cardiac rate decreases and cardiac arrest occurs.^{199, 200} Stanbury²⁰¹ has shown that the magnesium ion has a blocking action on sympathetic ganglions, the cardiac slowing may therefore be related to this effect as well as to direct cardiac depression. In dogs magnesium sulfate has been found to be of some value in preventing ventricular arrhythmias due to mercurial diuretics.²⁰²

Although magnesium sulfate has been found to be of value in various types of paroxysmal tachycardia,²⁰³⁻²⁰⁷ similar doses have little effect on the normally beating human heart.^{203, 208}

Method of administration Intravenous doses range from 10 to 20 cc of a 10 to 30 per cent (in most cases, 20 to 25 per cent) solution of magnesium sulfate in distilled water.

It appears that the concentration of the drug reaching the heart is the important factor, accordingly, intravenous injection is accomplished in twenty to thirty seconds. If there is any effect on the arrhythmia, it occurs at once.

Side effects and contraindications An unpleasant though transient generalized feeling of intense heat and an associated drop in blood pressure (20 to 30 systolic) may occur^{204, 206} immediately after the intravenous administration of magnesium sulfate. There may also be perspiration, flushing, dizziness, frequently nausea but rarely vomiting and a transient feeling of generalized weakness. Ventricular premature beats may be observed for a short period.²⁰⁶ It has been suggested²⁰⁶ that magnesium sulfate should not be used in the presence of marked myocardial damage, intraventricular-conduction de-

Dosage Schedules

Schedules of quinidine administration for prophylactic and therapeutic purposes differ considerably and must be established in accordance with the requirements of a particular case.

Prophylactic administration In many patients with recurrent paroxysms, attacks are so infrequent and mild that continued administration of quinidine is not warranted. Prophylactic administration is instituted only when paroxysms of tachycardia tend to recur frequently or when single paroxysms are serious because of their severity or their nature (for example, ventricular tachycardia). In such patients individualization of dosage is important; initial doses of 0.2 gm. three times a day, if inadequate to prevent recurrence of the paroxysms, may be followed by larger doses and more frequent administration; 1.0-gm. doses have been given repeatedly for long periods.⁵¹ In certain persons it may be necessary to arrange the doses to minimize the interval between the last night and the first morning dose. In these cases enteric-coated tablets may be of value. Because of the rapidity with which quinidine is eliminated, long-continued administration carries no danger of cumulative toxicity, and the drug has been administered regularly for years without ill effect.^{51, 135}

Quinidine is often used to prevent the occurrence of arrhythmias, which may develop during acute myocardial infarction and thoracic surgery. In patients with acute myocardial infarction 0.2 to 0.3 gm. is customarily administered three or four times during the day. In view of the unpredictability of the occurrence of these arrhythmias, the efficacy of such prophylaxis is difficult to evaluate. When necessary, the size of the individual dose can be increased to 0.4 or 0.6 gm.

In patients undergoing thoracic surgery, quinidine is often used prophylactically during the operation and the early postoperative period. A dose of 0.4 to 0.6 gm. is administered by mouth or intramuscularly one or two hours before the operation and continued every six to eight hours for a few days postoperatively.

Therapeutic administration In the treatment of an acute arrhythmia the urgency of the situation will influence considerably the manner in which quinidine is administered. Effective therapeutic results can be achieved with oral administration, but when necessary the drug may be given intramuscularly. In most cases, with oral or intramuscular routes, doses are repeated at intervals of about two hours. This permits observation of the maximum beneficial and untoward effect of each dose. When a more rapidly increasing effect is required, the drug may be given every hour.

An initial dose of 0.2 to 0.6 gm. is commonly used, the larger amount being given in the more urgent situation. A favorable response is mani-

fested by definite cardiac slowing, rise in blood pressure, decrease in symptoms or improvement in the patient's general condition. If this occurs after the first dose, the same dose may be repeated every two hours as long as improvement continues. Usually, if normal sinus rhythm has not returned after three or four such doses, the size of the dose is increased by 0.1 or 0.2 gm. This dose may then be given three or four times before it is increased further.

If a favorable response is not seen after the first dose, the second dose should be 0.1 or 0.2 gm. larger than the first, and subsequent doses may similarly be increased. In most cases individual doses do not often need to be raised above 1.2 gm. before normal rhythm is restored.

In the treatment of chronic auricular fibrillation many different dosage schedules have been recommended. As utilized by us, the drug is administered every four hours, and the size of the individual dose increased by 0.2 gm. every twelve to twenty-four hours. Ample time is therefore afforded to observe the effect of a particular level of quinidine. In the past, the drug has too often been declared ineffective in this disorder after inadequate trial because arbitrary fixed schedules have been followed.

Summary

Physiologic and pharmacologic data accumulated in the past few years, although providing a more rational basis for the use of quinidine, are as yet incomplete. Quinidine is of outstanding value in the management of paroxysmal ventricular tachycardia; its relative efficacy in other paroxysmal arrhythmias has not been established.

MISCELLANEOUS MEASURES

Grouped in this section are other drugs that have been used in the prevention and treatment of cardiac arrhythmias. Several — for example, procaine, quinacrine and Metrazol — are of value for other clinical conditions, and others — such as morphine, Paredrine and Neo-Synephrine — are useful in the treatment of certain effects consequent to a rapid heart rate, such as pain, restlessness, hypotension and peripheral vascular collapse. These drugs are listed in Table 1. Further studies of these drugs may lead to better treatment of cardiac arrhythmias. It is likely that some drugs on the list have been unjustifiably credited with prophylactic or therapeutic value. The establishment of rational methods for using older agents in these disorders may be as important as, if not more important than, the development of new ones. As pointed out above in the first two sections of this review, the multiplicity of measures used in cardiac arrhythmias has resulted in inadequate study of most of them.

The various surgical procedures that have been carried out on the sympathetic nervous system (Table 1) have had a very limited use, generally for

prophylactic purposes, in patients whose repeated paroxysms of tachycardia have not been prevented by medical measures

Digitalis Glycosides

The main indication for the use of cardiac glycosides is congestive heart failure regardless of the rhythm. Digitalis preparations are widely used in patients with paroxysmal supraventricular tachycardia, auricular fibrillation and auricular flutter particularly if heart disease is present and the paroxysmal nature of the tachycardia is not clear. The mechanism of action of digitalis in preventing and stopping auricular arrhythmias is obscure. It is important to remember that paroxysmal tachycardia of ventricular origin is considered by many to represent a contraindication to digitalis therapy.

Choice of preparation The various considerations governing the selection of a digitalis glycoside have been the subject of a recent report.¹⁹¹ Numerous digitalis preparations have been used intravenously in the treatment of acute supraventricular arrhythmias. Although a great deal of emphasis has been placed on lanatoside C intravenously,^{59, 195, 196} there is no clear evidence that it accomplishes more than other digitalis preparations such as Digalen,⁵⁹ Digifolin⁶⁷ and ouabain.¹⁹⁷ Oral preparations have been used to prevent the recurrence of these arrhythmias.¹⁹⁵

Side effects The evidences of digitalis overdosage are well known. In the various studies with intravenous lanatoside C mentioned above, only occasional nausea and rare transient ventricular extrasystoles have been observed.

Efficacy in treatment of paroxysmal supraventricular arrhythmias Rapid restoration of normal rhythm has been observed after half to full "digitalizing" doses of cardiac glycosides intravenously in patients with paroxysmal auricular tachycardia, paroxysmal auricular fibrillation and paroxysmal auricular flutter. In many cases the effect occurred within five to ten minutes of the injection. In others, the change in rhythm occurred after a longer interval, up to twenty-four hours, and the relation to the drug was therefore not definite. In some cases ventricular slowing may be noted although normal sinus rhythm is not restored. This may result in symptomatic improvement, and unless electrocardiograms are taken sinus rhythm may be thought to have returned.

In several cases of paroxysmal auricular tachycardia Weisberger and Feil⁵⁹ found that carotid-sinus pressure although previously ineffective, stopped the attack immediately when applied after the administration of lanatoside C. This is in accord with the observation that digitalis increases the sensitivity of the carotid-sinus reflex.^{40, 60} A similar effect has been seen, as pointed out above in the first section, after acetyl-beta-methyl-choline and neostigmine.

Efficacy in preventing paroxysmal supraventricular arrhythmias Tandowsky¹⁹⁵ has maintained digitalization with 0.5 to 1.0 mg of lanatoside C by mouth daily in 8 patients with paroxysmal auricular flutter and auricular tachycardia. Only three attacks occurred during a fifteen-month period of treatment, compared to twenty-four during a twelve-month period prior to digitalization. Although the observations were not completed by the omission of digitalis to determine if the frequency of attacks increased the results are consistent with our own experience.

Summary Digitalis preparations are of value in the prevention and treatment of paroxysmal supraventricular arrhythmias. The intravenous route of administration has been found particularly useful in stopping paroxysms of tachycardia. These substances can be given safely in therapeutic doses and may be expected to be effective in many patients and may of course be of value for associated cardiac failure.

Magnesium Sulfate

High concentrations of magnesium ion depress the cardiac conduction system and heart muscle. As the serum concentration of magnesium ion is increased in animals, prolongation of the PR and QRS intervals is observed, the cardiac rate decreases and cardiac arrest occurs.^{199, 200} Stanbury²⁰¹ has shown that the magnesium ion has a blocking action on sympathetic ganglions, the cardiac slowing may therefore be related to this effect as well as to direct cardiac depression. In dogs magnesium sulfate has been found to be of some value in preventing ventricular arrhythmias due to mercurial diuretics.²⁰²

Although magnesium sulfate has been found to be of value in various types of paroxysmal tachycardia,^{203, 204} similar doses have little effect on the normally beating human heart.^{203, 205}

Method of administration Intravenous doses range from 10 to 20 cc of a 10 to 30 per cent (in most cases 20 to 25 per cent) solution of magnesium sulfate in distilled water.

It appears that the concentration of the drug reaching the heart is the important factor, accordingly, intravenous injection is accomplished in twenty to thirty seconds. If there is any effect on the arrhythmia, it occurs at once.

Side effects and contraindications An unpleasant though transient generalized feeling of intense heat and an associated drop in blood pressure (20 to 30 systolic) may occur^{204, 206} immediately after the intravenous administration of magnesium sulfate. There may also be perspiration, flushing, dizziness, frequently nausea but rarely vomiting and a transient feeling of generalized weakness. Ventricular premature beats may be observed for a short period.²⁰⁶ It has been suggested²⁰⁶ that magnesium sulfate should not be used in the presence of marked myocardial damage, intraventricular-conduction de-

fects or gallop rhythm. Since magnesium is excreted largely by the kidneys,⁷⁶ it should be used with care in the presence of renal failure.²⁰³

Efficacy in treatment of various arrhythmias. Beneficial action has been reported²⁰³⁻²⁰⁷ in paroxysmal supraventricular tachycardia, paroxysmal ventricular tachycardia and ventricular premature beats due to digitalis. The effect, especially in the digitalis-induced extrasystoles, has sometimes been only transient. Increase in auriculoventricular block has been seen in auricular flutter but, in general, no beneficial effect has been observed in this arrhythmia or in auricular fibrillation.

Summary. Magnesium sulfate has been less widely used in the management of paroxysmal tachycardias than the digitalis glycosides and other agents. Its short duration of action makes its prophylactic use impractical. Therapeutically, it appears to be effective in many cases, but its use is associated with transient unpleasant side effects.

SUMMARY OF THERAPEUTIC PROGRAMS IN THE ARRHYTHMIAS

The large number of available measures for the management of paroxysmal arrhythmias poses a considerable problem for the physician. It is pertinent, therefore, that we summarize our own programs in the various arrhythmias.

Paroxysmal Supraventricular Tachycardia

Carotid-sinus and eyeball pressure are simple, safe means of reflex vagal stimulation, effective often enough to warrant their trial as the initial procedures in all cases. These measures, particularly carotid-sinus stimulation, should be repeated frequently along with some of the miscellaneous measures discussed above.

If these simple measures fail, sedation (by barbiturates) and rest are often associated with restoration of normal rhythm. In the absence of pulmonary congestion, angina pectoris, congestive failure, vascular collapse, cerebral manifestations or embolism this nonspecific therapy may be continued for twenty-four to forty-eight hours or longer before other measures are used. Neostigmine, Neosynephrine, Paredrine or acetylcholine may then be administered particularly in young persons with normal hearts. If parasympathomimetic drugs are used (such as Neostigmine) reflex vagal stimulation should be repeated. Although previously ineffective carotid-sinus stimulation a few minutes after administration of these drugs often stops an attack. Although ipecac is unpleasant because of the necessary association of vomiting with its beneficial action it is safe, and we have used it successfully. In the patient with cardiac disease, especially if congestive failure is present and the simple reflex measures mentioned above have failed, digitalis is the drug of choice. Quinidine is of value in many cases refractory to these measures.

If the tachycardia persists, other agents reported to be of value, such as magnesium sulfate, potassium salts, procaine and quinacrine may be tried.

Paroxysmal Auricular Fibrillation and Paroxysmal Auricular Flutter

It should be emphasized that in most cases sedation and rest alone may be accompanied by reversion to normal sinus rhythm. If not, and in the presence of symptoms, the choice of therapy lies between quinidine and digitalis. In young persons without heart disease we use quinidine. In the presence of heart disease or congestive failure, or both, digitalis is the drug of choice.

Chronic Auricular Fibrillation

When treatment is necessary, digitalis is used. In some unusual cases of congestive failure or embolism due to arrhythmia, quinidine has been used successfully.

Ventricular Extrasystoles

The avoidance of tobacco and coffee and the use of sedatives are very often beneficial. If not, quinidine, in doses outlined above, may be used effectively.

Paroxysmal Ventricular Tachycardia

Quinidine is the drug of choice if specific treatment is necessary. The dosage schedules have been given above. In refractory cases, other drugs, such as magnesium sulfate, potassium salts, diethylaminoethanol and morphine, may be tried.

fects or gallop rhythm. Since magnesium is excreted largely by the kidneys,⁷⁶ it should be used with care in the presence of renal failure.²⁰³

Efficacy in treatment of various arrhythmias. Beneficial action has been reported^{203, 207} in paroxysmal supraventricular tachycardia, paroxysmal ventricular tachycardia and ventricular premature beats due to digitalis. The effect, especially in the digitalis-induced extrasystoles, has sometimes been only transient. Increase in auriculoventricular block has been seen in auricular flutter but, in general, no beneficial effect has been observed in this arrhythmia or in auricular fibrillation.

Summary. Magnesium sulfate has been less widely used in the management of paroxysmal tachycardias than the digitalis glycosides and other agents. Its short duration of action makes its prophylactic use impractical. Therapeutically, it appears to be effective in many cases, but its use is associated with transient unpleasant side effects.

SUMMARY OF THERAPEUTIC PROGRAMS IN THE ARRHYTHMIAS

The large number of available measures for the management of paroxysmal arrhythmias poses a considerable problem for the physician. It is pertinent, therefore, that we summarize our own programs in the various arrhythmias.

Paroxysmal Supraventricular Tachycardia

Carotid-sinus and eyeball pressure are simple, safe means of reflex vagal stimulation, effective often enough to warrant their trial as the initial procedures in all cases. These measures, particularly carotid-sinus stimulation, should be repeated frequently along with some of the miscellaneous measures discussed above.

If these simple measures fail, sedation (by barbiturates) and rest are often associated with restoration of normal rhythm. In the absence of pulmonary congestion, angina pectoris, congestive failure, vascular collapse, cerebral manifestations or embolism this nonspecific therapy may be continued for twenty-four to forty-eight hours or longer before other measures are used. Neostigmine, Neo-Synephrine, Paredrine or acetylcholine may then be administered, particularly in young persons with normal hearts. If parasympathomimetic drugs are used (such as Neostigmine) reflex vagal stimulation should be repeated. Although previously ineffective, carotid-sinus stimulation a few minutes after administration of these drugs often stops an attack. Although ipecac is unpleasant because of the necessary association of vomiting with its beneficial action, it is safe, and we have used it successfully. In the patient with cardiac disease, especially if congestive failure is present and the simple reflex measures mentioned above have failed, digitalis is the drug of choice. Quinidine is of value in many cases refractory to these measures.

If the tachycardia persists, other agents reported to be of value, such as magnesium sulfate, potassium salts, procaine and quinacrine may be tried.

Paroxysmal Auricular Fibrillation and Paroxysmal Auricular Flutter

It should be emphasized that in most cases sedation and rest alone may be accompanied by reversion to normal sinus rhythm. If not, and in the presence of symptoms, the choice of therapy lies between quinidine and digitalis. In young persons without heart disease we use quinidine. In the presence of heart disease or congestive failure, or both, digitalis is the drug of choice.

Chronic Auricular Fibrillation

When treatment is necessary, digitalis is used. In some unusual cases of congestive failure or embolism due to arrhythmia, quinidine has been used successfully.

Ventricular Extrasystoles

The avoidance of tobacco and coffee and the use of sedatives are very often beneficial. If not, quinidine, in doses outlined above, may be used effectively.

Paroxysmal Ventricular Tachycardia

Quinidine is the drug of choice if specific treatment is necessary. The dosage schedules have been given above. In refractory cases, other drugs, such as magnesium sulfate, potassium salts, diethylaminoethanol and morphine, may be tried.

DIFFERENTIAL DIAGNOSIS

DR JOHN CRAWFORD The important facts seem to be the following: this five-month-old infant was entirely well until seven days before death. For one week he had had diarrhea amounting to eight stools daily, which were liquid and yellow at first, becoming green but without blood.

In the infant under one year of age diarrhea is a frequent symptom of extra-enteral infection. Nowadays, with milk pasteurization and good refrigeration, diarrhea due to true enteral infection is becoming less and less common. I think we may guess that the child had a parenteral infection, probably an upper respiratory infection, with diarrhea as the chief symptom.

Apparently, this mother of three children had had previous experience with infantile diarrhea and immediately began limitation of solid food. When this failed to alleviate the difficulty the family physician was called. We are not told what he found. My guess is that he found evidence of a pharyngitis or otitis media, for which he prescribed sulfonamides. He also prescribed bismuth and paregoric, which sometimes are effective in quieting a mild diarrhea but rarely in severe diarrhea.

On the day before death the infant began to refuse fluids, and it was said that his urine was pink, this, from subsequent findings, apparently being due to blood. His condition rapidly deteriorated, for the next day he was taken to a hospital, where he was found to be in a critical condition.

The physical examination at that hospital showed a drowsy, dehydrated infant, with a temperature of 103°F and an upper respiratory infection. Edema of the penis and scrotum was noted, without edema elsewhere. The urine was grossly bloody. Evidently no casts were seen. We are told that the urine contained 90 mg of albumin per 100 cc. This is not a great deal: the commonly used heat and acetic acid test would be interpreted as + to ++ with this degree of albuminuria. We do not know whether the urine was concentrated or dilute.

A considerable anemia was present. The prematurely born infant of five months ordinarily has about 10 gm of hemoglobin. This infant had 8.7 gm. I would interpret this figure to represent a marked deviation from normal in view of the clinical dehydration. Serum chemical analyses revealed a nonprotein nitrogen of 37.7 mg per 100 cc, a startlingly high figure; the blood sulfonamide level was only 1.4 mg per 100 cc.

In short, the infant was obviously critically ill. He was given emergency treatment consisting of blood to correct the anemia, fluid to combat dehydration and penicillin for infection, and was then referred with all dispatch to this hospital.

Following arrival here we learn little more to help in making the diagnosis before death. The child was in collapse, he had episodes of convulsive

movements. One observer thought that he had hypertension. He died only two hours after admission.

There are several diagnoses to be considered. The older texts say that syphilitic nephritis is the commonest hemorrhagic nephritis in infants under one year of age. In this part of the country congenital syphilis is seen with ever-diminishing frequency. I would expect the protocol to mention syphilis in the mother or a positive blood test in the child if this merited further consideration.

A sulfonamide tubular nephrosis due to crystal formation might be considered, but there are several points against this diagnosis. The physician treating the infant wisely used a mixture of three sulfonamide drugs so that the antibacterial effect would be proportional to the sum of the serum concentrations of each, and yet the danger of renal precipitation in the face of diarrhea would be minimal since the solubility of each sulfonamide component is independent of the other two in the renal tubular fluid. Furthermore, the blood sulfonamide level of 1.4 mg per 100 cc, obtained twenty-four hours or less after the last dose in an oliguric patient, is indicative of conservative use of the drug.

The child might have had a sulfonamide-sensitivity nephritis. This would be unexpected so soon after the initial dose. We have no history of prior sulfonamide administration, which might account for an accelerated reaction.

Acute hemorrhagic nephritis is a definite possibility. We have evidence of a preceding respiratory infection, which might well have been streptococcal. We have hematuria, oliguria, nitrogen retention and possibly hypertension with encephalopathy.

To make this diagnosis I should like to have the report of granular casts in a concentrated urine. Such an extremely high nonprotein nitrogen is unusual. There was less albuminuria than I would expect. Moreover the disease itself, while very common in childhood, is distinctly rare in the infant under six months. I cannot rule out acute hemorrhagic nephritis, but I do not believe that it fits the clinical picture as well as another diagnosis.

Although a transfusion nephrosis seems unlikely, since the symptoms were well established before the giving of blood, it might be mentioned that there is some evidence that transfusion of blood in which the plasma complement titer is high may aggravate an already existing glomerulonephritis.

The diagnosis I favor here is that of "hemorrhagic infarction of the kidney." Quite a large number of cases have been reported in infancy, particularly as a complication of diarrheal episodes. Barenberg¹ and Hepler² have reported a considerable number of cases in infancy.

I would suppose that the sequence of events in this infant was as follows: seven days before death

CASE 35421

PRESENTATION OF CASE

A five-month-old-male infant was admitted to the hospital because of diarrhea

The patient was born prematurely of a pregnancy that was complicated by kidney disease diagnosed as pyelitis. However, the baby's development had been entirely normal, and three siblings were living and well. A week before admission he began to have diarrhea that did not respond to limitation of solid foods, passing about eight liquid stools a day, which were yellow at first and later green. Two days before admission a physician prescribed a mixture of triple sulfonamides, bismuth and paregoric of which an unknown amount was taken over the next twenty-four hours. On the following day the fluid intake was only 5 ounces, and the mother

noted that the baby's urine was pink. On the day of admission the baby was seen at another hospital, where physical examination showed a drowsy, dehydrated infant with a temperature of 103°F and a pink diaper stain. There was edema of the penis and scrotum and a mild pharyngitis. The urine was packed with red cells and contained 90 mg per 100 cc of albumin. The hemoglobin was 8.7 gm per cent, the red-cell count 2,700,000, and the white-cell count 11,500, with 66 lymphocytes, 32 per cent mature neutrophils, 1 per cent stab cells, and 1 per cent basophils. The blood was type O and Rh+. The nonprotein nitrogen was reported as 377 mg per 100 cc, the sulfonamide level was 1.4 mg per 100 cc. He was given a 180-cc infusion of 5 per cent glucose in physiologic saline solution, 80 cc of whole blood and 300,000 units of procaine penicillin, and referred to this hospital.

On admission the baby was pale, comatose and gasping. The eyes were turned up, and there were convulsive movements of the right arm. Coarse bubbling rales were heard bilaterally. The heart rate was 140 without murmurs. The systolic blood pressure was thought to be 140 by one observer. A blood culture was later reported as negative.

Oxygen and artificial respiration were begun immediately, and after some thirty minutes the baby improved. However a second left-sided convulsion followed, subsiding without treatment. He was then given 0.16 mg of Cedilamid intravenously and 15 mg of phenobarbital subcutaneously. At this point a third convulsion occurred, and the baby stopped breathing.

In spite of artificial respiration, oxygen, caffeine and sodium benzoate intravenously and 0.5 cc of epinephrine injected into the heart, the infant died two hours after admission to the hospital.

DIFFERENTIAL DIAGNOSIS

DR JOHN CRAWFORD The important facts seem to be the following this five-month-old infant was entirely well until seven days before death. For one week he had had diarrhea amounting to eight stools daily, which were liquid and yellow at first, becoming green but without blood.

In the infant under one year of age diarrhea is a frequent symptom of extra-enteral infection. Nowadays, with milk pasteurization and good refrigeration, diarrhea due to true enteric infection is becoming less and less common. I think we may guess that the child had a parenteral infection, probably an upper respiratory infection, with diarrhea as the chief symptom.

Apparently, this mother of three children had had previous experience with infantile diarrhea and immediately began limitation of solid food. When this failed to alleviate the difficulty the family physician was called. We are not told what he found. My guess is that he found evidence of a pharyngitis or otitis media, for which he prescribed sulfonamides. He also prescribed bismuth and paregoric, which sometimes are effective in quieting a mild diarrhea but rarely in severe diarrhea.

On the day before death the infant began to refuse fluids, and it was said that his urine was pink, this, from subsequent findings, apparently being due to blood. His condition rapidly deteriorated, for the next day he was taken to a hospital, where he was found to be in a critical condition.

The physical examination at that hospital showed a drowsy, dehydrated infant, with a temperature of 103°F and an upper respiratory infection. Edema of the penis and scrotum was noted, without edema elsewhere. The urine was grossly bloody. Evidently no casts were seen. We are told that the urine contained 90 mg of albumin per 100 cc. This is not a great deal; the commonly used heat and acetic acid test would be interpreted as + to ++ with this degree of albuminuria. We do not know whether the urine was concentrated or dilute.

A considerable anemia was present. The prematurely born infant of five months ordinarily has about 10 gm of hemoglobin. This infant had 8.7 gm. I would interpret this figure to represent a marked deviation from normal in view of the clinical dehydration. Serum chemical analyses revealed a nonprotein nitrogen of 377 mg per 100 cc, a startlingly high figure, the blood sulfonamide level was only 1.4 mg per 100 cc.

In short, the infant was obviously critically ill. He was given emergency treatment consisting of blood to correct the anemia, fluid to combat dehydration and penicillin for infection, and was then referred with all dispatch to this hospital.

Following arrival here, we learn little more to help in making the diagnosis before death. The child was ~~in collapse~~, he had episodes of convulsive

movements. One observer thought that he had hypertension. He died only two hours after admission.

There are several diagnoses to be considered. The older texts say that syphilitic nephritis is the commonest hemorrhagic nephritis in infants under one year of age. In this part of the country congenital syphilis is seen with ever-diminishing frequency. I would expect the protocol to mention syphilis in the mother or a positive blood test in the child if this merited further consideration.

A sulfonamide tubular nephrosis due to crystal formation might be considered, but there are several points against this diagnosis. The physician treating the infant wisely used a mixture of three sulfonamide drugs so that the antibacterial effect would be proportional to the sum of the serum concentrations of each, and yet the danger of renal precipitation in the face of diarrhea would be minimal since the solubility of each sulfonamide component is independent of the other two in the renal tubular fluid. Furthermore, the blood sulfonamide level of 1.4 mg per 100 cc, obtained twenty-four hours or less after the last dose in an oliguric patient, is indicative of conservative use of the drug.

The child might have had a sulfonamide-sensitivity nephritis. This would be unexpected so soon after the initial dose. We have no history of prior sulfonamide administration, which might account for an accelerated reaction.

Acute hemorrhagic nephritis is a definite possibility. We have evidence of a preceding respiratory infection, which might well have been streptococcal. We have hematuria, oliguria, nitrogen retention and possibly hypertension with encephalopathy.

To make this diagnosis I should like to have the report of granular casts in a concentrated urine. Such an extremely high nonprotein nitrogen is unusual. There was less albuminuria than I would expect. Moreover the disease itself, while very common in childhood, is distinctly rare in the infant under six months. I cannot rule out acute hemorrhagic nephritis, but I do not believe that it fits the clinical picture as well as another diagnosis.

Although a transfusion nephrosis seems unlikely, since the symptoms were well established before the giving of blood, it might be mentioned that there is some evidence that transfusion of blood in which the plasma complement titer is high may aggravate an already existing glomerulonephritis.

The diagnosis I favor here is that of "hemorrhagic infarction of the kidney." Quite a large number of cases have been reported in infancy, particularly as a complication of diarrheal episodes. Barenberg¹ and Hepler² have reported a considerable number of cases in infancy.

I would suppose that the sequence of events in this infant was as follows: seven days before death

he had contracted an upper respiratory infection that resulted in moderate diarrhea. The day before entry, possibly as a result of factors such as dehydration and diminished blood volume, thromboses began to form in the small vessels of the kidneys, with resultant hematuria and oliguria. This process, once initiated, extended very rapidly and may have involved not only the blood vessels of the kidney but also those of the pelvis, giving rise to the peculiar edema of the penis and scrotum observed on physical examination. The extravasation of blood into the infarcted renal tissues resulted in the marked anemia and contributed to the extreme elevation of the nonprotein nitrogen. When this condition is bilateral or goes unrecognized for any length of time, collapse and death soon result.

Campbell and Matthews³ emphasize that the diagnosis should be made clinically on the basis of the history and on the physical finding of firm flank masses. However, Barenberg,¹ describing 5 cases in infants, was unable to palpate a swollen kidney in any of them.

In summary, then, the protocol suggests to me either acute hemorrhagic nephritis following a streptococcal respiratory infection or so-called "acute hemorrhagic infarction" of the kidney. Of these two diagnoses, the latter seems to fit the few facts outlined in the protocol somewhat better than the former.

CLINICAL DIAGNOSIS

Acute hemorrhagic nephritis

DR CRAWFORD'S DIAGNOSES

Diarrhea due to acute pharyngitis
Dehydration secondary to diarrhea
Acute hemorrhagic infarction of kidneys

ANATOMICAL DIAGNOSES

Ischemic necrosis of kidneys
Pulmonary edema
Petechial hemorrhages in brain

PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY: Dr Crawford's prediction is, I think, essentially correct. The only major lesion at autopsy was found in the kidneys, which were markedly enlarged and grossly hemorrhagic. Microscopical examination showed a picture, which to me is unfamiliar in infancy, of extensive necrosis, predominantly in the cortex, though some foci were present in the pyramids. This necrosis was most marked in the tubules and was present to a less degree in the glomeruli. We could find no thrombosed vessels anywhere in the kidneys. There were a few small areas in which complete infarct-like necrosis with interstitial hemorrhage was present. The majority of the kidney showed a much less severe, degenerative process from which one would, I think, assume that recovery might

have been possible. The major part of the blood evident on gross examination lay in the lumen of the tubules, giving evidence that there had been massive leakage of blood through the glomerular tufts, and, quite often, Bowman's capsule was found acutely distended with red cells.

Other parts of the body showed what I think were only secondary features: extensive pulmonary atelectasis and edema and multiple, minute petechial hemorrhages throughout the brain — a not too uncommon complication of uremia.

DR ALFRED KRANES: How does the picture differ from bilateral cortical necrosis?

DR MALLORY: It is very similar, and that is, in fact, the diagnosis that I made.

DR KRANES: Does that occur in infants?

DR MALLORY: Dr Crawford knows more about that than I do, and I would like to ask him.

DR CRAWFORD: I tried to emphasize that I put "acute hemorrhagic infarction" in quotation marks because I did not think it was a good descriptive term. In the pediatric literature "acute hemorrhagic infarction" is used to describe a condition that seems to be very similar to the "acute cortical necrosis" of the adult literature. The terms probably refer to the same disease.

DR MALLORY: I think there is very little doubt that it is the same condition. My only hesitancy in calling it acute cortical necrosis was the fact that there was some involvement of the pyramids, which is unusual, at least in the adult cases of cortical necrosis. Cortical necrosis is seen most commonly in pregnancy, but it can occur in other conditions, and in the male as well as the female. It has been seen in association with a variety of infections and occasionally follows shock and burns. Vascular thrombosis may or may not be present and may well be secondary rather than primary. I suspect that this is also true of the lesion described as "renal thrombosis with infarction" in the pediatric literature.

CASE 35422

PRESENTATION OF CASE

First admission. A fifty-five-year-old Greek barber was admitted to the hospital because of swelling of the legs, genitalia and abdomen.

The patient was well until some eight years before admission, when he first began to notice evening ankle edema, which subsided on rest at night. This persisted until about two months before entry, when the swelling became progressively worse and no longer cleared by morning. This was followed

soon afterward by swelling of the genitalia and, to a lesser extent, the abdomen. During the month before admission he had experienced a sense of discomfort in both upper quadrants, with sharp pain on deep breathing. He also noticed a three-flight exertional dyspnea without orthopnea. There was no history of nausea or vomiting, hematemesis, melena or recent jaundice. His appetite was good, but he had lost about 15 pounds in weight during the last eighteen months. The patient gave a history of painless jaundice some twenty-five years before. He stated that he drank two or three glasses of wine a day. One week before admission the patient was seen in the Outpatient Clinic where diuretics were administered with marked diminution of swelling.

The patient had a penile lesion twenty years before and was treated with thirty intravenous injections.

Physical examination revealed a well developed and well nourished man in no acute distress. There was slight icterus of the skin and scleras but no spider angiomas. The chest was clear except for a few rales in the right base. The liver edge was palpated two or three fingerbreadths below the right costal margin, and the spleen two fingerbreadths below the left costal margin. There were many prominent veins over the abdomen and shifting dullness without a fluid wave. Tenderness was present in both upper quadrants. There were several external hemorrhoidal tabs, and the prostate was slightly enlarged. The lower legs showed a ++ edema, varicosities and pigmentation of the skin.

The temperature was 99°F, the pulse 80, and the respirations 20. The blood pressure was 95 systolic, 60 diastolic.

The urine was yellow and cloudy and had a specific gravity of 1.012. It gave a +++ test for albumin but contained no bile. There were 20 to 30 white cells per high-power field in the sediment. A urine smear showed rare clusters of gram-positive cocci and a urine culture grew *Staphylococcus albus*. The blood hemoglobin was 10 gm, and the white-cell count 3800, with 56 per cent neutrophils. The blood nonprotein nitrogen was 40 mg, and the total protein 7.11 gm per 100 cc, with an albumin of 3.55 gm and a globulin of 3.56 gm. The fasting blood sugar was 124 mg per 100 cc, and the cephalin flocculation test was ++ and ++++ in twenty-four and forty-eight hours, the thymol turbidity was 13.5 units, the cholesterol 241 mg and cholesterol esters 115 mg per 100 cc. The prothrombin time was 15 seconds (normal, 15 seconds). The serum van den Bergh reaction was 0.6 mg per 100 cc direct and 0.8 mg indirect, and the alkaline phosphatase 5.2 units per 100 cc. A bromsulfalein test showed 36 per cent retention of the dye. A blood Hinton test was positive.

A gastrointestinal series was negative. No varices were identified. The spleen was enlarged, and a

roentgenogram of the chest showed only slight prominence of the left ventricle. A phenolsulfonephthalein test showed normal excretion, and a urea-clearance test gave specific gravities of 1.012, 1.015 and 1.015. The patient was advised concerning a high-calorie, high-protein, low-sodium diet and was discharged on the ninth hospital day somewhat improved. During this period in the hospital daily afternoon temperature rose to about 100°F. Four separate urine specimens showed 5 to 40 white cells per high-power field in the sediment and had specific gravities that ranged from 1.012 to 1.015. On two occasions the urine contained occasional granular and hyaline casts.

Final admission (approximately two months later). In the interval the patient noted progressive weakness and loss of appetite. One month before entry swelling of the legs, genitalia and abdomen again became marked despite diuretic therapy. An abdominal paracentesis was performed by a physician, with the removal of a considerable amount of fluid, but the abdominal swelling soon recurred. His skin became increasingly more jaundiced, and he had experienced nausea and vomiting during the three days before admission.

The findings on physical examination were essentially the same as those at the time of the previous admission, with the addition of pulsating neck veins.

The temperature was 99°F, pulse 80, and the respirations 20. The blood pressure was 136 systolic, 76 diastolic.

The urine had a specific gravity of 1.020 and gave a ++ test for albumin and bile. The sediment contained 2 or 3 red cells and 6 to 8 white cells and many hyaline and granular casts per high-power field. The blood hemoglobin was 9.5 gm and the white-cell count 6000, with 74 per cent neutrophils. The red cells showed moderate anisocytosis and hypochromia. The blood nonprotein nitrogen was 35 mg, and the total protein 7.85 gm per 100 cc, with an albumin of 3.08 gm and a globulin of 4.77 gm. The cephalin flocculation test was +++ and ++++ in twenty-four and forty-eight hours. The serum van den Bergh reaction was 6.0 mg per 100 cc direct and 8.4 mg indirect, and the alkaline phosphatase was 5.4 units per 100 cc. The prothrombin time was 21 seconds (normal, 15 seconds).

The patient became increasingly more drowsy and icteric, ate little and vomited frequently. The edema did not respond to the usual therapy. On the eighth hospital day after being comatose for twenty-four hours, he died.

DIFFERENTIAL DIAGNOSIS

DR JACOB LERMAN. I should like to know if mention is made of treatment for the urinary infection during the first admission.

DR TRACY B MALLORY There is no notation about therapy for pyelitis

DR LERMAN The initial symptoms could be explained either by right-sided heart failure or by the beginning of portal obstruction or portal cirrhosis. The slow development of edema, first in the legs and then in the abdomen, and finally the enlargement of the liver suggest the course of events that one sees in right-sided failure. However, he had no symptoms of right-sided failure. Mention is made of three-flight dyspnea. That is normal for all of us. There was no respiratory distress on examination. In spite of the type of onset, there was no evidence of cardiac involvement. He had an episode of painless jaundice, which does not seem to have much bearing on the problem. No doubt the intake of wine is of importance in this particular eastern Mediterranean race. He had evidence of acquired syphilis as indicated by a positive blood Hinton reaction, it may have played an important role.

On physical examination he had mild icterus, enlargement of the liver and spleen, fluid in the abdomen, prominent veins over the abdomen, hemorrhoids, varicosities and edema of the legs—all of which fit the diagnosis of portal cirrhosis. I cannot explain why he had such a low blood pressure. Undoubtedly he had a urinary infection. Evidence in the record indicates some degree of pyelonephritis. In addition, the abdominal pain, the anemia, the leukopenia, the reversed albumin-globulin ratio, the positive cephalin-flocculation test, the low cholesterol esters of 115 mg per 100 cc of a total of 241 mg, the bromsulfalein retention all speak for liver damage of the type one sees in portal cirrhosis. I assume that the fever was due to urinary infection, although fever is not uncommon in cirrhotic patients.

May we see the x-ray films?

DR JAMES J McCORT An examination of the gastrointestinal tract was made at the time of admission. The spot films of the esophagus show normal rugae without evidence of varices. The stomach shows no definite abnormality. There is a small diverticulum in the third portion of the duodenum. It is apparent that the spleen is enlarged and pressing on the stomach. There is also some enlargement of the left lobe of the liver as shown by the compression of the stomach.

The chest film taken on admission reveals clear lung fields. The heart is slightly prominent in the region of the left ventricle, there is no bulging anteriorly to indicate right-sided heart enlargement. It can be seen that the right leaf of the diaphragm is slightly higher than usual. A film of the chest at the time of the second admission, two months later, discloses an increase in vascular markings in both lung fields. The right leaf of the diaphragm is higher, and there is a small amount of fluid in the right costophrenic angle, posteriorly. A slight

under-aeration of the right lower lobe may be secondary to the high right leaf of the diaphragm.

DR LERMAN Can you judge whether or not the left lobe of the liver is the larger portion?

DR McCORT No, a film of the entire abdomen was not obtained.

DR LERMAN The subsequent rapid downhill course, in addition to the x-ray appearance of increased vascular congestion and the pulsating neck veins, again raises the question of congestive failure. It may be just incidental to the major problem. As I said before, all the facts so far seem to favor a diagnosis of ordinary portal cirrhosis.

We must consider other diagnoses such as syphilitic cirrhosis or gumma of the liver. The additional evidence that the left lobe of the liver was large is a characteristic finding in syphilitic cirrhosis. This is not sufficient evidence, however, to make the diagnosis, but it is suggestive. On the other hand, it is difficult to know whether syphilitic cirrhosis is different from ordinary portal cirrhosis. Many people believe that they are one and the same thing. Gumma is somewhat different. A gumma usually appears in the left lobe. It is the only suggestive bit of evidence. Hemochromatosis may be mentioned because he had pigmentation of the leg, but he did not have pigmentation elsewhere or evidence of diabetes. I assume that the pigmentation was due to stasis dermatitis associated with varicosities. Amyloid disease should be mentioned, even though there was no obvious cause for amyloidosis, other than possibly cirrhosis itself. The presence of a large liver and spleen and the albuminuria are consistent with a diagnosis of amyloidosis. Unfortunately, we have no other evidence, such as a Congo-red test. We can only mention it. Even primary amyloidosis might be a possibility.

Hepatoma should be mentioned, particularly in view of the rapid downhill course following the initial admission. The description of the liver is certainly not suggestive of hepatoma. Yet, in the presence of cirrhosis of long standing, rapid downhill course and weight loss, there is a good possibility that he had hepatoma. This produced sufficient obstruction to the biliary radicles to cause rapid liver failure.

We should also discuss the cause of death. Obviously he died from cholemia. What are the possibilities? I have already mentioned the co-existence of hepatoma. In addition, a patient with cirrhosis is rather subject to episodes of hepatitis or degeneration of the liver. I have seen several patients with portal cirrhosis who suddenly developed acute or subacute yellow atrophy or some sort of change in the cells that may be labeled hepatitis. The course here would suggest that he developed some such process as subacute yellow atrophy.

I must conclude with a diagnosis of portal cirrhosis, probably hepatoma, and probably a super-

imposed subacute degenerative process, such as subacute yellow atrophy

DR ALFRED KRAVES When Dr Lerman says "portal" does he mean of the so-called alcoholic type?

DR LERMAN Yes

DR KRAVES May not the previous history of jaundice have been a factor in the later development of cirrhosis? It is hard to tell from the history. One wonders if it was due to arsenic. Apparently he had syphilis twenty years previously and was treated with arsenic.

DR LERMAN One would expect the late damage from arsenic or hepatitis to develop within a few years, or there would be recurrent episodes of this damage as is so often observed following hepatitis — until it ends up in biliary cirrhosis.

CLINICAL DIAGNOSES

Cirrhosis of liver
Infectious hepatitis

DR LERMAN'S DIAGNOSES

Portal cirrhosis
Hepatoma — probable
Subacute yellow atrophy — probable

ANATOMICAL DIAGNOSES

Cirrhosis of liver portal
Hepatoma, with extension into vena cava and
right auricle of heart, and pulmonary metastases
Esophageal varices
Thrombosis of portal vein

PATHOLOGICAL DISCUSSION

DR MALLORY The exterior surface of the liver showed the coarse granularity characteristic of

a long-standing cirrhosis. The dome of the right lobe showed in addition a large nodule 6 cm in diameter that projected upward 2 to 3 cm from the surrounding tissue. When the liver was sectioned sagittally it was evident that the inferior vena cava was completely filled with a tumor thrombus that extended up into the right auricle of the heart. Tracing the tumor backward in sections of the liver, it was obvious that the hepatic veins were occluded, and there was a primary tumor in the liver substance occupying a considerable part of the right lobe. Histologically, it was a hepatoma, a primary liver-cell carcinoma, developing as it almost invariably does in a liver that has been cirrhotic for a long period. The cirrhosis itself was old and inactive. Beyond saying that it was a portal cirrhosis, I cannot classify it further. I cannot say whether or not it might have been a result of previous hepatitis or a result of alcoholism — greater than admitted. There was evidence of acute degeneration of liver cells in many parts of the organ itself, infarct-like in character and secondary to the numerous vascular occlusions. No distant metastases were found grossly, but in microscopical sections of the lung a very large proportion of the minute pulmonary arteries were solidly plugged with tumor thrombi, and quite probably in the terminal days or few weeks of life there was pulmonary hypertension and an element of cor pulmonale.

DR EDWARD B. BENEDICT How common are tumor thrombi with hepatoma?

DR MALLORY Four cases out of 5 invade the intrahepatic veins, usually the hepatic, sometimes the portal radicles. It is an exceptional case in which the tumor thrombus occludes the vena cava and grows into the right auricle, but we have seen it on several occasions. The one other tumor in which invasion of veins is equally extensive is hypernephroma, which can also grow up the vena cava and directly in the auricle.

OCTOBER MEETING OF THE COUNCIL

THE fall meeting of the Council of the Massachusetts Medical Society was held on October 5 with President Arthur W. Allen in the chair. Owing in some part at least to a careful screening of the Society's business by the Executive Committee, the Council nearly broke a record for neatness and dispatch in the performance of its functions.

The deaths of two councilors, Dr. Harold G. Giddings, of Middlesex South, and Dr. Henry A. Robinson, of Norfolk South, was announced, and solemn tribute was paid to their memories.

Various matters of interest and importance were considered by the Council and disposed of according to their merits. Important among these was the approval of the creation of a new representative committee, composed of the secretaries of the district societies, to study the question of redistricting the Society and changing the ratio of representation in the Council.

Dr. Elmer S. Bagnall, of Essex North, a former president of the Society, held in warm regard and widely recognized for the intelligent devotion with which he has served his profession and his community, was unanimously acclaimed as the Society's candidate for the General Practitioner's Award of the American Medical Association.

On recommendation of the Committee on Public Relations, the Council voted to establish a Massachusetts Medical Society citation to be awarded to a layman or a group of laymen for outstanding contributions to medical progress. No more than three such awards are to be made in any one year. It was proposed that this award be named in honor of Lemuel Shattuck, onetime bookseller of Boston and perhaps the country's most distinguished lay contributor to progress in public health. This opportunity was rejected.
